EXECUTIVE SUMMARY

Stormwater Treatment Area 1 West (STA-1W) is a constructed wetland that is part of the Everglades Construction Project mandated by Florida's Everglades Forever Act [Section 373.4592, Florida Statutes]. It was built as an expansion of the Everglades Nutrient Removal Project (ENR), a constructed wetland to demonstrate the effectiveness of phosphorus (P) removal from agricultural runoff/drainage. The ENR was operated for five years (1994 to 1999) and STA-1W started operation on July 1, 1999. STA-1W covers 2,772 hectares (6,849 acres) and is located in south Florida (26° 38' N, 80° 25' W) at the eastern edge of the Everglades Agricultural Area. The Everglades Agricultural Area is a 240,000 ha (593,000 ac), highly productive irrigation drainage basin with a major production of sugarcane. Ecological changes in the Everglades have been partially attributed to an increase in phosphorus (P) concentrations in the inflow waters. Local, state and federal initiatives have been taken to reduce P load from agricultural runoff/drainage. Water from the agricultural area flows to the south and southeast through four primary canals: Miami, North New River, Hillsboro and West Palm Beach.

A minimum of 25 percent of the P load from the EAA is required to be removed at the basin level through the application of various agricultural Best Management Practices (BMPs) (Whalen and Whalen, 1994). Further removal of P is to be achieved through constructed wetland treatment systems, known as Stormwater Treatment Areas (STAs), to an initial outflow total P concentration of 0.05 milligrams per liter (mg L^{-1}). STA-1W is one of the large-scale constructed wetlands that followed the successful operation of the ENR Project. This report presents the third annual water budget for STA-1W (July 1, 2001 to June 30, 2002). Water budget analyses for five years of the ENR Project and two years of STA-1W were reported in South Florida Water Management District technical publications (Guardo et al., 1996; Abtew and Mullen, 1997; Abtew and Downey, 1998; Abtew et al., 2000; Abtew et al., 2001).

The total inflow into STA-1W through the inflow spillway for the study period (July 1, 2001 to June 30, 2002) was 36,065 hectare-meters (ha-m) or 292,372 acre-feet (ac-ft), and the total outflow through the outflow pumps was 41,798 ha-m (338,848 ac-ft). Estimated seepage inflow from the L-7 levee through the roadside culverts was 439 ha-m (3,559 ac-ft). The seepage recirculation pump had a total flow of 1,716 ha-m (13,911 ac-ft). Total areal average rainfall for the study period was 138.1 centimeters (cm), or 54.4 inches (in), and the total areal average evapotranspiration was 133 cm (52.4 in). A comparison with the previous period's (July 1, 2000 to June 30, 2001) water budget shows that surface water inflow for this period was four times that of the last period, indicating that the 2000-2001 drought is over (Abtew et al., 2002).

The mean hydraulic loading rate for the study period, based on daily average inflow, was 3.56 centimeters per day (cm d^{-1}), or 1.4 inches per day (in d^{-1}). The mean hydraulic retention time was computed as the ratio of the mean estimated volume of STA-1W and the average of inflow and outflow. The mean estimated volume was computed from the area-weighted (by cell) mean depth of 62 cm (24.4 in) and total area of 2,772 ha (6,849 ac). The estimated mean hydraulic retention time was 16.1 days and that is the lowest for the three years of STA-1W operation.

INTRODUCTION

Background

Stormwater Treatment Area 1 West (STA-1W) is a constructed wetland that is part of the Everglades Construction Project mandated by Florida's Everglades Forever Act [Section 373.4592, Florida Statutes]. It was built as an expansion of the Everglades Nutrient Removal Project (ENR), a constructed wetland to demonstrate the effectiveness of phosphorus (P) reduction from agricultural runoff/drainage. The ENR was operated for five years (1994 to 1999), and STA-1W started operation on July 1, 1999. STA-1W covers 2,772 hectares (6,849 acres) and is located in South Florida (26° 38' N, 80° 25' W) at the eastern edge of the Everglades Agricultural Area (Figure 1). The Everglades Agricultural Area is a 240,000 ha (593,000 ac), highly productive basin with a major production of sugarcane. Ecological changes in the Everglades have been partially attributed to an increase in phosphorus (P) concentrations in the inflow waters. Local, state and federal initiatives have been taken to reduce P load from agricultural runoff/drainage. Agricultural runoff/drainage from the agricultural area flows to the south and southeast through four primary canals, shown in Figure 1: Miami, North New River, Hillsboro and West Palm Beach.

A minimum of 25 percent of the P load from the EAA is required to be removed at the basin level through the application of various agricultural Best Management Practices (BMPs) (Whalen and Whalen, 1994). Further removal of P is to be achieved through constructed wetland treatment systems, known as Stormwater Treatment Areas (STAs), to an initial outflow total P concentration of 0.05 milligrams per liter (mg L^{-1}). STA-1W is one of the large-scale constructed wetlands that followed the successful operation of the ENR Project. This report presents the third annual water budget for STA-1W (July 1, 2001 to June 30, 2002). Water budget analyses for five years of the ENR Project and two years of STA-1W were reported in South Florida Water Management District technical publications (Guardo et al., 1996; Abteu and Mullen, 1997; Abteu and Downey, 1998; Abteu et al., 2000; Abteu et al., 2001).

Site Description

A survey of the ENR Project indicated that the area is primarily covered by Okeechobee muck soils where one to two meters of peat overlies several meters of carbonate rock (Jammal and Associates, Inc., 1991). The topography of STA-1W is relatively flat, with an average ground elevation of 2.99 m (9.79 ft) NGVD. To the east, the L-7 levee separates STA-1W from the Arthur R. Marshall Loxahatchee National Wildlife Refuge (Water Conservation Area 1, WCA-1). The seepage canal runs along the northern perimeter, the discharge canal on the west separates STA-1W from agricultural land. The narrow southern ENR levee separates STA-1W from the discharge area into WCA-1. STA-1W consists of five cells (Cells 1, 2, 3, 4 and 5). Cell 1 and Cell 3, and Cell 2 and Cell 4 are two parallel treatment trains of pairs of cells from the previous ENR. As shown in Figure 2, the largest cell, Cell 5, has been added to the north. The total area of STA-1W is 2,772 ha (6,849 acres). Table 1 depicts the area and average ground elevation for each cell.

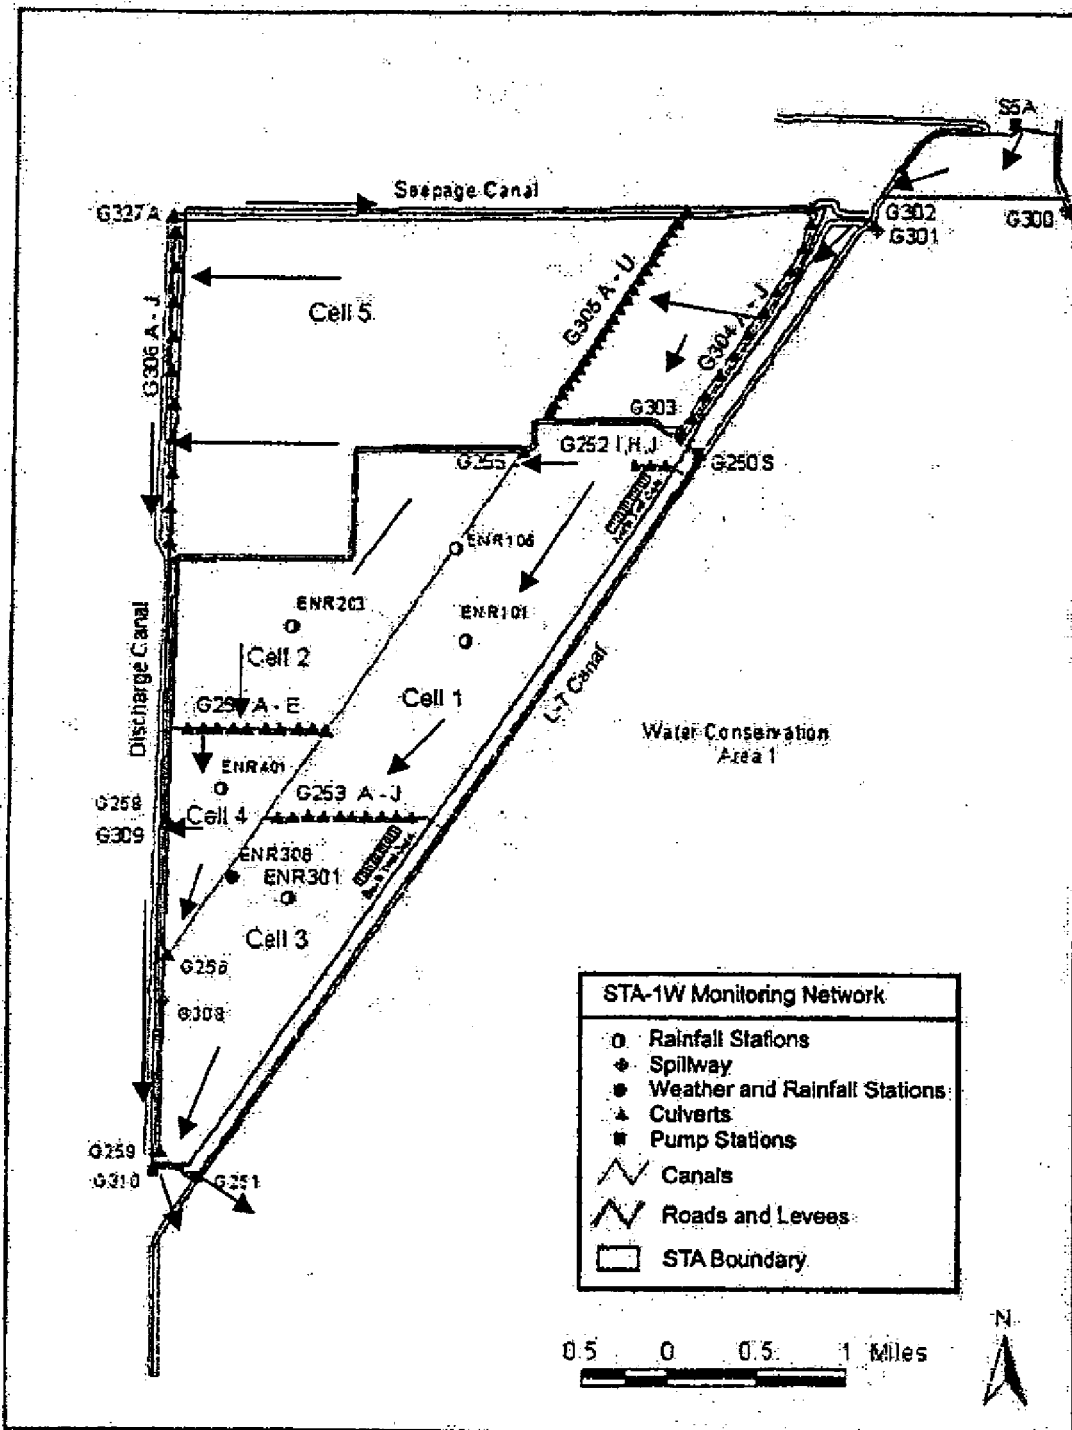

Figure 2. STA-1W structures and monitoring network

Vegetation Cover

STA-1W vegetation cover generally varies from cell to cell but is mainly dominated with cattails (*Typha* sp.) or submerged aquatic vegetation (SAV). Cell 1 is covered mostly with emergent vegetation dominated by cattail (*Typha* sp.), but the cell also contains significant submerged aquatic vegetation. A small portion of Cell 1 contains the floating aquatics water hyacinth (*Eichhorina crassipes*) and water lettuce (*Pistia stratiotes*). Also, leather fern (*Acrostichum* sp.), carolina willow (*Salix caroliniana*) and primrose willow (*Ludwigia* sp.) are present in Cell 1. Cell 2 is mostly covered with emergent vegetation dominated by cattail, but the cell also contains significant submerged aquatic vegetation and periphyton. A small portion of Cell 2 contains the floating aquatics water hyacinth (*Eichhorina crassipes*) and water lettuce (*Pistia stratiotes*). Cell 3 is mostly covered with emergent vegetation dominated by cattail, but also contains significant coverage of pickerelweed (*Pontederia cordata*), arrowhead (*Sagittaria latifolia*), duck potato (*Sagittaria lancifolia*), spikerush (*Eleocharis* sp.) and carolina willow (*Salix caroliniana*). Cell 4 is covered with submerged aquatic vegetation dominated by southern naiad (*Najas guadalupensis*), coontail (*Ceratophyllum demersum*), and pondweed (*Potamogeton illinoensis*) with naturally occurring periphyton. Cell 5A (eastern) is covered with mixed vegetation containing cattail (*Typha* sp.), SAV (*Najas guadalupensis*), the floating aquatics water hyacinth (*Eichhorina crassipes*) and water lettuce (*Pistia stratiotes*). Cell 5B (western) is covered with submerged aquatic vegetation dominated by southern naiad (*Najas guadalupensis*), coontail (*Ceratophyllum demersum*) and hydrilla (*Hydrilla verticillata*) with naturally occurring periphyton. Also, small amounts of cattail (*Typha* spp.) and water hyacinth (*Eichhorina crassipes*) are present (Richard Meeker, South Florida Water Management District, personal communication).

SYSTEM HYDRAULICS AND OPERATION

System Hydraulics

STA-1W Inflow and Distribution

West Palm Beach (C-51) canal water that otherwise would have been pumped into the Loxahatchee National Wildlife Refuge (WCA-1) via the S5A pump station and would have flowed through the Refuge is diverted to STA-1W. A small portion of the area of WCA-1 near the S5A pump station is leveed and forms the STA-1 Inflow and Distribution (STA-1 I & D) that serves as a storage area to divert water into STA-1W and into STA-1E (when it is built). There are two old and four new water control structures in the STA-1 I & D. The S5A pump station delivers water from C-51 (West Palm Beach canal); the S5AS spillway controls WCA-1 inflow and outflow at the junction of L-8 and C-51. The junction has culvert structures S5AW and S5AE. The four new spillway structures are G300, G301, G302 and G311.

G300 is a two-bay, reinforced concrete, U-shaped spillway with vertical lift gates installed on the crest of ogee-shaped weirs. The purpose of this structure is to bypass flows from the STA-1 I & D area into the L-40 borrow canal that runs along the eastern edges of WCA-1. G301 is a three-bay, reinforced concrete, U-shaped spillway with vertical lift gates on weirs. The purpose of this structure is to bypass flow from the STA-1 I & D area into WCA-1 along the L-7 borrow canal on the western edge of WCA-1. G302 is a fixed-crest, concrete ogee spillway equipped with two vertical lift gates each of which are 6 meters (20 ft) wide. The purpose of this structure is to supply inflow to the five cells of STA-1W from the STA-1 I & D area. G302 has a capacity of $92 \text{ m}^3 \text{ s}^{-1}$ (3,250 cfs). G311 is designed as a three-bay, reinforced concrete spillway with lift gates on weirs. The purpose of this structure is to supply water for the future STA-1E from the STA-1 I & D area. Information for STA-1W structures is provided in Table 2. Structure locations are shown in Figure 2.

STA-1W Inflow, Internal, and Discharge Structures

The supply canal to STA-1W is about 2.72 km (1.7 miles) long, extending between the inflow structure G302 and the structure controlling flow into Cells 1, 2, 3 and 4 (G303). The canal has side slopes of 2.5:1, with a bottom width of 18.3 m (60 ft) at elevation -1.52 m (-5 ft) NGVD. Expected velocities in the inflow canal vary between 0.232 m s^{-1} (0.76 ft s^{-1}) and 0.418 m s^{-1} (1.37 ft s^{-1}) (Hutcheon Engineers, 1996). G303 is a two-bay ogee spillway equipped with two lift gates each 4.9 m (16 ft) wide and with a discharge capacity of $50.4 \text{ m}^3 \text{ s}^{-1}$ (1780 cfs).

Perimeter and inter-cell levees facilitate vehicle transportation within the wetland. The levees have culverts underneath for inflows, outflows and inter-cell water delivery. Under each levee, the culverts are spread along the levee to facilitate distribution of flow over the downstream cell area. The evenness of flow distribution depends on the ground surface elevations and vegetation cover of the receiving cell.

Upstream of Cell 1 and Cell 2, there was a buffer cell that received flow from G250S (seepage return pumps) and the inflow spillway G303. There was a levee with 10 culverts (G252A-J) between the buffer cell and Cell 1. The transition to STA-1W involved degrading about 70 percent of the levee and removing all but three of the culverts (G252H, I, J). The number of culverts between the buffer cell and Cell 2 was five (G255A-E) but was increased to seven (G255A-G) in the transition from ENR to STA-1W making direct connection between Cell 1 and Cell 2. Similarly, there were five G254 culverts between Cell 2 and Cell 4 under the ENR Project, but they were increased to nine as part of STA-1W (G254 A, A1, B, B1, C, C1, D, D1, and E). The levee between Cell 1 and Cell 3 has 10 culverts G253 (A-J), which did not change in the transition from ENR to STA-1W. Between Cell 4 and Cell 3 there are five culverts (G256A-E), which were not affected by the change from ENR to STA-1W.

Inflow to Cell 5 is through ten 29.3 m (96 ft) long corrugated metal pipe culverts (G304A-J). The combined capacity of the inflow culverts (G304A-J) is $41.6 \text{ m}^3 \text{ s}^{-1}$ (1,470 cfs). The Florida Power and Light (FPL) levee runs across Cell 5, dividing the cell into two parts. Twenty-two culverts (G305A-V) were constructed to deliver water from the eastern part to the western part of the cell. Each of the G305 culverts is 213 cm (84 inches) in diameter and 27.4 m (90 ft) long, with an invert elevation of 1.07 m (3.5 ft) NGVD. Seepage and recirculated water from Cell 5 is pumped through G250S to Cell 1 through the old ENR buffer cell, which is now part of Cell 1. G250S has three main pumps with a combined capacity of $5.66 \text{ m}^3 \text{ s}^{-1}$ (200 cfs), and three supplemental pumps from the old ENR inflow pump station G250 with a combined capacity of $8.49 \text{ m}^3 \text{ s}^{-1}$ (300 cfs).

At the west end of Cell 3 are two outflow structures releasing to the discharge canal, G308 and G259. Similarly, G258 and G309 are the two outflow structures releasing to the discharge canal from Cell 4, located at the west end. Hydraulic information for internal structures is shown in Table 3.

Outflow from Cell 5 to the discharge canal is through 10 corrugated metal pipes of 183 cm (72 in) in diameter and 39.6 m (130 ft) long with a combined discharge capacity of $41.6 \text{ m}^3 \text{ s}^{-1}$ (1,470 cfs). G327A is a gated culvert 213 cm (84 in) in diameter, and 39.6 m (130 ft) long with $2.83 \text{ m}^3 \text{ s}^{-1}$ (100 cfs) discharge capacity. G327C is a culvert 39.3 m (129 ft) long and with a $2.83 \text{ m}^3 \text{ s}^{-1}$ (100 cfs) discharge capacity. STA-1W outflow structures are the G251 and G310 pump stations. G251 has six identical pumps with a combined capacity of $12.74 \text{ m}^3 \text{ s}^{-1}$ (450 cfs). G310 is equipped with six pumps of three different capacities, with a total capacity of $86 \text{ m}^3 \text{ s}^{-1}$ (3,040 cfs). G310 has two electric pumps with a combined discharge capacity of $5.66 \text{ m}^3 \text{ s}^{-1}$ (200 cfs), two diesel pumps, with a combined discharge capacity of $26.6 \text{ m}^3 \text{ s}^{-1}$ (940 cfs), and two diesel pumps with a combined discharge capacity of $53.8 \text{ m}^3 \text{ s}^{-1}$ (1,900 cfs).

Discharge from Cell 1 into Cell 3 flows through ten 183-cm (72 in) diameter and 17.7-m (58 ft) long culverts (G253A-J). Discharge from Cell 2 into Cell 4 flows through nine 183-cm (72 in) diameter and 16.5-m (54 ft) long culverts (G252A, A1, B, B1, C, C1, D, D1 and E). Discharge from Cell 3 is to the discharge canal through G308 and G259 and to WCA-1 through the G251 pump station. G308 is a gated weir with a discharge capacity of $15.85 \text{ m}^3 \text{ s}^{-1}$ (560 cfs). G259 is a gated culvert 183 cm (72 in) in diameter and 23.9 m (78.5 ft) long. Discharge from Cell 4 is into the discharge canal through G309, G258 and into Cell 3 through G256A-E. G309 is a gated weir with a discharge capacity of $15.85 \text{ m}^3 \text{ s}^{-1}$ (560 cfs). G258 is a gated culvert 183 cm (72 in) in diameter and 23.5 m (77 ft) long. G256A-E consists of five culverts 183 cm (72 in) in diameter and 16.6 m (54.5 ft) long.

The discharge canal extends between G327A at the northwest corner and the G310 pump station at the southwestern corner. The discharge canal is about 9.12 km (5.7 miles) long with bottom width varying from 15.2 m (50 ft) at G327A to 24.4 m (80 ft) at G308 and to 30.5 m (100 ft) at G259, to account for changes in flow magnitude and ground elevation.

Operation

S5A diverts water from the West Palm Beach canal into the STA-1 I&D area. From the STA-1 I & D area, water flows to STA-1W through spillway G302 or can be bypassed to WCA-1 through G300 and G301 when necessary. Water flows into Cell 5 via the inflow canal and through culverts G304 A-J and into treatment Cells 1, 2, 3 and 4 through gated weir structure G303. The old ENR seepage pumps (G250S) control stages in the seepage canal north of treatment Cell 5 and redirect flow to the old ENR (Cells 1, 2, 3 and 4).

Culverts, installed beneath G302, deliver seepage return flow to G250S pumps. The pumps, in turn, convey the seepage return flow into Cell 1, which also receives inflow from G303, as well. Thus, flow is primarily direct (open surface flow) and partly through the remaining culverts (G252 H, I and J). Cell 2 receives flow from Cell 1 through culverts G255 (A-G). From Cell 1, water flows to Cell 3 through the G253 (A-J) culverts. Water delivery between Cell 2 and Cell 4 is through nine culverts (G254 A, A1, B, B1, C, C1, D, D1 and E). Outflow from STA-1W is through pump stations G251 and G310. One objective of the operation was to maintain stage in Cell 5 at 3.41 m (11.2 ft) NGVD, with a fluctuation of 0.06m (0.2 ft).

HYDROLOGY AND HYDROLOGIC MONITORING

Rainfall

STA-1W has a six-gage rainfall monitoring network. Table 4 lists all the rainfall gaging stations, the corresponding database keys and the respective Thiessen weights. Figure 2 shows the gage locations. Areal average rainfall on the project site was computed as a Thiessen-weighted average of the six-gage network. Minimal data gaps at a station would be estimated, while extended gaps result in areal rainfall computation using remaining stations with a new set of Thiessen weights. The daily distribution of areal average rainfall for the study period (July 1, 2001 to June 30, 2002) is depicted in Figure 3. Monthly summary of areal average rainfall for STA-1W is shown in Table 5. The total areal average rainfall for STA-1W (July 1, 2001 to June 30, 2002) was 138.1 cm (54.4 in). The seven-year average areal rainfall for the previous ENR constructed wetland and the current STA-1W, from July 1, 1994 to June 30, 2001, was 136.1 cm (53.6 inches).

Table 4. Rainfall stations in STA-1W, database retrieval keys and Thiessen weights

Stations	DBKEY	Theissen Weights

ENR301	15877	0.126
ENR308	15888	0.049
ENR401	15862	0.075

Evapotranspiration

Daily evapotranspiration is computed from high-resolution weather data using a radiation-based evapotranspiration estimation model that was developed based on lysimeter studies in the ENR (Abtew, 1996a, 1996b). A complete weather station is located in Cell 3 (ENR308). The daily distribution of evapotranspiration for STA-1W for the study period (July 1, 2001 to June 30, 2002) is depicted in Figure 3. Monthly summary of evapotranspiration for STA-1W is shown in Table 5. The total evapotranspiration for STA-1W (July 1, 2001 to June 30, 2002) was 133 cm (52.4 inches). The six-year average areal ET for the previous ENR and current STA-1W (July 1, 1995 to June 30, 2000) was 133.3 cm (52.5 inches).

Flows

Database keys for STA-1W flow structures and stage gages are listed in Table 6. The total inflow spillway discharge for the study period (July 1, 2001 to June 30, 2002) was 36,065 ha-m (292,372 ac-ft), and the total outflow through the outflow pump stations was 41,798 ha-m (338,848 ac-ft). The daily pumping rates of the inflow and outflow pumps are shown in Figure 4. Figure 5 shows estimated seepage from the L-7 levee flowing through the roadside culverts and the daily seepage recycling pumping. The total seepage and recirculation pumping was 1,716 ha-m (13,911 ac-ft). The L-7 seepage through the roadside culverts was estimated using a regression equation developed from 42 data points. A relationship was developed between the seepage from L-7 through the roadside culverts, the stage rise in WCA-1 above 4.57 m (15 ft) NGVD, and the difference in stages between WCA-1 and the eastern cells of the ENR (Guardo, 1996). The regression had a coefficient of determination (R^2) of 0.93 and a standard error of $0.30 \text{ m}^3 \text{ s}^{-1}$ (Equation 1). The total estimated seepage from L-7 through the roadside culverts was 439 ha-m (3,559 ac-ft). Monthly flow data for the study period are presented in Table 5.

$$L7a = 0.217\Delta WCA^{1.311} * \Delta h^{2.025} \quad (1)$$

Where $L7a$ is seepage in $\text{m}^3 \text{ s}^{-1}$, ΔWCA is rise in stage in WCA-1 above 4.57 m (15 ft) NGVD and Δh is the difference in stage between WCA-1 and the eastern cells of STA-1W.

Water Levels

Daily water levels in each cell of STA-1W depend on rainfall, evapotranspiration, seepage and daily operational decisions. Water levels have been regulated based on water depth, operation status of the S5A pump station and maintenance. The minimum, maximum and mean of the daily average stage observations for the study period are shown in Table 7. The mean observed stage in Cell 1 was 3.75 m (12.3 ft) NGVD. The mean stage in Cell 2 was 3.75 m (12.3 ft) and the mean stage in Cell 3 was 3.66 m (12.00 ft) NGVD. The

mean stage in Cell 4 was 3.70 m (12.15 ft) NGVD, and the mean stage in Cell 5 was 3.47 m (11.38 ft) NGVD. Average daily stages for Cell 5 were computed from stage readings for G304 tailwater and G306 headwater. Average daily water level observations in Cells 1 and 3 of STA-1W and WCA-1 are shown in Figure 6. Water levels for Cells 2 and 4 are shown in Figure 7. Figure 8 shows daily water levels for Cell 5. The mean water depths for Cells 1, 2, 3, 4 and 5 were 62 cm (24.4 in), 81 cm (31.9 in), 56 cm (22.0 in), 70 cm (27.6 in) and 45 cm (22.4 in), respectively.

WATER BUDGET COMPUTATIONS

STA-1W Water Balance Model

A schematic hydrologic model for STA-1W is depicted in Figure 9. The inflow supplied through the G302 spillway accounts for about 78 percent of the known inflow to the system. The known inflows to the system are G302 spillway inflows, rainfall and seepage through the roadside L-7 levee culverts (L-7a). Rainfall accounts for 8.3 percent, and seepage through the roadside culverts (L-7a) accounts for 0.9 percent. Outflow pumping (G251 and G310) accounts for 91.9 percent of the outflows, with evapotranspiration constituting 8.1 percent of the total outflows. The unknowns in the system are ungaged subsurface inflows, outflows and errors that account for 12.8 percent of the total inflows. The schematic model (Figure 9) and the following set of water balance equations represent the hydrologic system of STA-1W for water budget analysis purposes.

$$INFLOW - OUTFLOW = \Delta S + \epsilon_T \quad (2)$$

where INFLOW is the amount of water that enters the system from external sources, and OUTFLOW is water that leaves the system boundary and is not recirculated. ΔS is the change in storage in the system during the time interval of interest. The sum of all errors is represented by ϵ_T . Because all inflow and outflow cannot be entirely quantified, the following equation is introduced to represent the remainders, errors and unknowns:

$$REMAINDERS = \epsilon_T + \text{UNKNOWN S} \quad (3)$$

Figure 9 shows the possible inflows and outflows to and from the STA-1W system. The seepage canal, which encompasses the northern side of STA-1W, is designed to capture seepage from STA-1W to the neighboring area and to recirculate discharge from the discharge canal when needed. Seepage through the old ENR supply canal is represented as SEEP1, and seepage in and out of the seepage canal to the north is represented as SEEP2. SEEP3 represents the two seepage possibilities into or out of the discharge canal to the west, regardless of the magnitude. SEEP4 represents the possible seepage loss or gain through the southern levee into the old Knight's Farm or WCA-1. The unmeasured seepage inflow from WCA-1 into STA-1W from the east is represented by L-7b.

In computing the water balance for STA-1W, it is essential to identify quantifiable variables from unquantifiable variables, making reasonable assumptions to reduce the quantity of unknowns as much as possible. Since the purpose of the seepage canal is to recirculate seepage and recycled water, it is assumed that the seepage return pump flows are recirculation in the system. This assumption does not rule out the possibility of external seepage inflow being part of recirculation flow. Change in storage is represented as follows:

$$\Delta S = G302 + R + L7a + L7b - G251 - G310 - ET - SEEP1 - SEEP2 - SEEP3 - SEEP4 + \epsilon_T \quad (4)$$

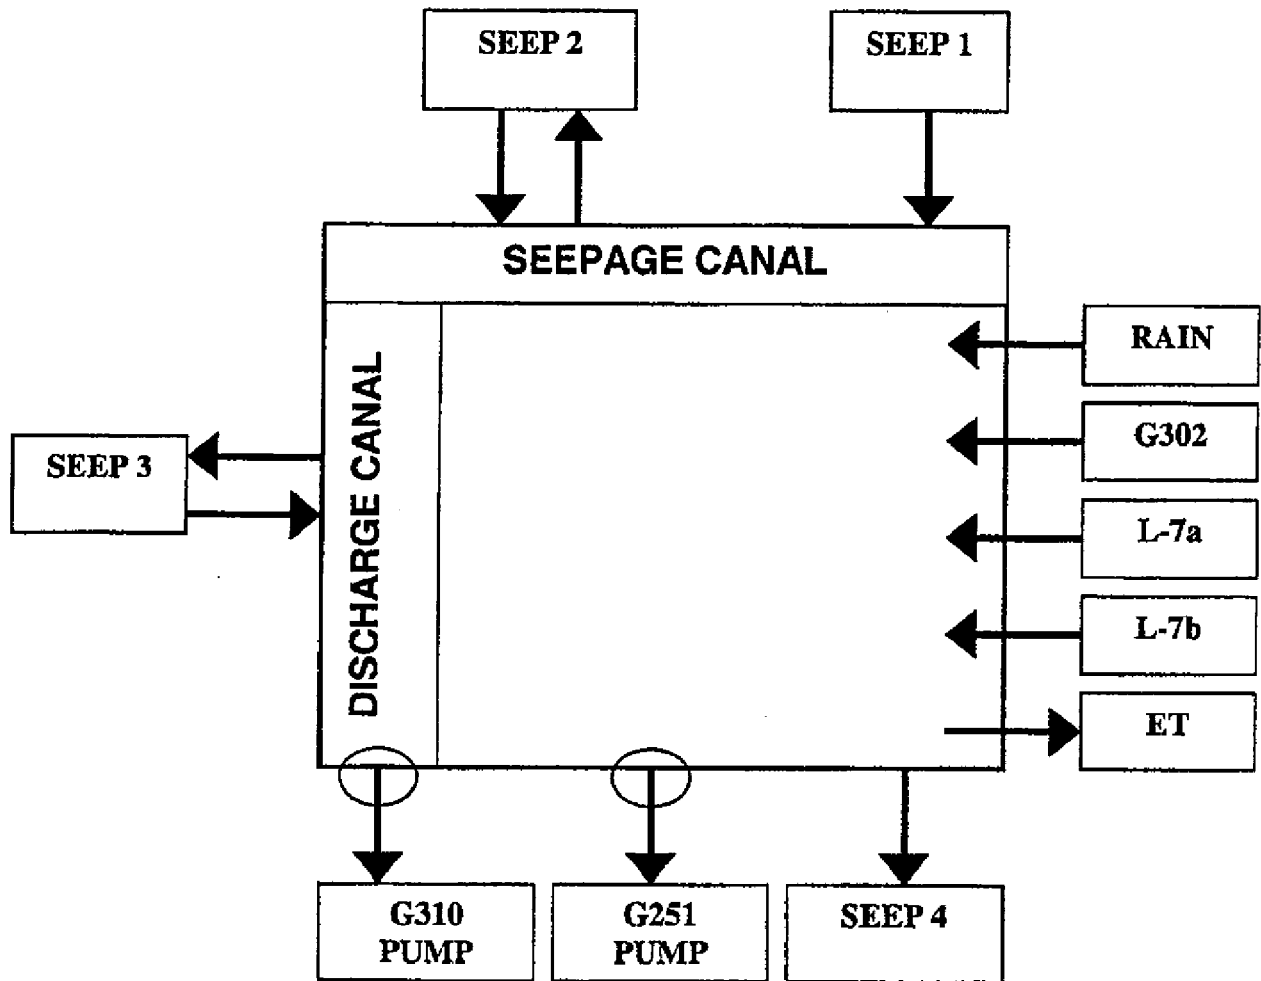

Figure 9. Schematic hydrologic model for STA-1W

where ΔS is change in storage in the system; G302 is inflow; R is rainfall; L-7a is seepage flow from WCA-1 through the roadside culverts; L-7b is unknown subsurface seepage flow from WCA-1 into STA-1W; ET is evapotranspiration losses. G310 and G251 represent outflow pumping; e_r represents total errors in inflow and outflow terms.

Daily change in storage for STA-1W was computed as the sum of storage changes in each of the five cells (Cell 1, Cell 2, Cell 3, Cell 4 and Cell 5). Change in storage volume in each cell was computed from the area of the cell and change in stage. The remainders in the computation of daily water balances are the sum of all errors and unknowns in the system. Daily remainders were computed for the one-year study period based on the following equation:

$$\text{REMAINDERS} = \Delta S - \text{INFLOWS} + \text{OUTFLOWS} \quad (5)$$

Discussion

The total inflow through the inflow spillway was 36,065 ha-m (292,372 ac-ft) and total outflow through the outflow pumps was 41,798 ha-m (338,848 ac-ft). Seepage inflow from the L-7 levee through the roadside culverts was a total of 439 ha-m (3,559 ac-ft). The seepage and recirculation pump had a total flow of 1,716 ha-m (13,911 ac-ft). Total average areal rainfall for the study period was 138.1 cm (54.4 inches) and the total average areal evapotranspiration was 133 cm (52.4 inches). For the study period, the mean daily remainders (errors and unknowns) was 16.3 ha-m per day, or 131.8 ac-ft per day, with the total remainder being 5,935 ha-m (48,114 ac-ft). The standard deviation of the remainders is 85.7 ha-m d⁻¹ (695 ac-ft d⁻¹), which signifies high variation. Figure 10 depicts the daily remainder distribution. The remainder is 12.8 percent of the total inflows. The negative remainder indicates that the overall outflow from the system is higher than the inflow.

Summary of the one-year water budget is shown in Table 8. Details of the water balance terms and calculation results are shown in Appendix I. The mean hydraulic loading rate for the study period, based on average flow, was 3.56 centimeters per day (cm d⁻¹), or 1.40 inches per day (in d⁻¹). The mean hydraulic retention time was computed as the ratio of the mean estimated water volume of STA-1W and the average daily flow rate. The estimated mean volume was computed from the area-weighted (by cell) mean depth of 62 cm (24.4 inches) and a total area of 2,772 ha (6,849 ac). The estimated mean hydraulic retention time was 16.1 days.

Figure 10. Distribution of daily remainders (errors and unknowns) from STA-1W water balance

WATER BUDGET SUMMARY

This water budget study covers the third year of operation of STA-1W (July 1, 2001 to June 30, 2002). For the period of analysis, the total inflow through the inflow spillway (G302) was 36,065 ha-m, or 292,372 ac-ft. The total outflow through the outflow pump (G251 and G310) was 41,798 ha-m (338,848 ac-ft). Seepage inflow from the L-7 levee through the roadside culverts was 439 ha-m (3,559 ac-ft). The seepage and recirculation pump had a total flow of 1,716 ha-m (13,911 ac-ft). Total areal average rainfall for the study period was 138.1 cm (54.4 in), and the total areal average evapotranspiration was 133 cm (52.4 in). The sum of the errors and unknowns was 5,935 ha-m (48,114 ac-ft), which equates to 12.8 percent of the total inflows to the system and indicates net seepage inflow into STA-1W and or negative errors in flow.

The mean hydraulic loading rate for the one-year period, based on average flow, was 3.56 cm d⁻¹ (1.40 in d⁻¹). The mean hydraulic retention time was computed as the ratio of the estimated mean volume of STA-1W and the average daily flow rate. The estimated mean volume was computed from the area-weighted (by cell) mean depth of 62 cm (24.4 inches) and a total area of 2,772 ha (6,849 ac). The estimated mean hydraulic retention time was 16.1 days. The change in storage was 785 ha-m or 6,364 ac-ft.

In STA-1W, all hydrologic parameters, with the exception of seepage through the system, are well monitored. Since the direction of seepage is not in one direction, the remainders (errors and unknowns) could not be allocated to one variable. Comparison of previous reporting period and current reporting period water budget parameters is depicted in Table 9. The current reporting period surface inflows and outflows are about four times larger than the last reporting period's water budget. The end of the drought

is demonstrated by the increase in flows, which has resulted in a bigger hydraulic loading rate and a smaller detention period.

Table 8. Summary of water budget for STA-1W (July 1, 2001 to June 30, 2002)

INFLOWS	ha-m	Percent of total	OUTFLOWS	ha-m	Percent of total
