EXECUTIVE SUMMARY

The Everglades Nutrient Removal Project (ENR) is a 1,544 hectare (ha) or 3,815 acre (ac) constructed wetland designed and operated for the demonstration of phosphorus (P) reduction from agricultural runoff/drainage. The ENR is located in south Florida ($26^{\circ} 38' N$, $80^{\circ} 25' W$) at the eastern edge of the Everglades Agricultural Area. The Everglades Agricultural Area is a 240,000 ha (593,000 ac) highly productive irrigation drainage basin with a major production of sugarcane. Ecological changes in the Everglades have been partially attributed to increase in phosphorus (P) concentrations in the inflow waters. Local, state and federal initiatives have been taken to reduce P load from agricultural runoff/drainage. Agricultural runoff/drainage from the agricultural area flows to the south and southeast through four primary canals (Miami, North New River, Hillsboro, West Palm Beach).

A minimum of 25% of the P load in agricultural drainage/runoff is required to be removed at the farm level through the application of various agricultural Best Management Practices. Further removal of P is to be achieved through constructed wetland treatment systems known as Stormwater Treatment Areas (STAs) to an initial outflow total P concentration of 0.05 milligrams per liter ($mg\ L^{-1}$). The ENR is a field scale prototype for the large scale STAs. It is built on farm land that is owned by the State of Florida and was previously leased (until 1988) to Knight's Farm for sugarcane and corn production. Construction of the ENR started in August 1992 and was completed in October 1993. Full operation started in August 1994. This report summarizes a two-year water budget analysis covering the period from August 19, 1994 to August 19, 1996.

The total inflow through the inflow pump was 39,000 hectare-meters (ha-m) or 316,115 acre-feet (ac-ft) and the total outflow through the outflow pump was 38,802 ha-m (314,560 ac-ft). Seepage inflow from the L-7 levee through the roadside culverts was a total of 1,198 ha-m (9,715 ac-ft). Total flow into the seepage canal through culverts G258 and G259 was 892 ha-m (7,231 ac-ft) and the seepage recirculation pump had a total flow of 7,143 ha-m (57,908 ac-ft). Total areal rainfall for the two-year study period was 328.7 centimeters (cm) or 129.4 inches (in) and the total areal evapotranspiration was 262.2 cm (103.2 in). The remainders in the water balance, the sum of the errors and unknowns, was 7% of the inflow or the outflow pumping or 6% of the sum of all outflows. The ENR is a new system with a relatively short period of hydrologic record. Longer periods of record are more favorable to characterize the operation and water balance of hydrologic systems.

ACKNOWLEDGEMENTS

Appreciation is extended to the Data Management Division of the Water Resources Evaluation Department for Instrumentation of the ENR hydrologic monitoring network, maintenance of the network, data collection, data processing and timely input to the database.

INTRODUCTION

Background

The Everglades Nutrient Removal (ENR) Project is a 1,544 hectare (ha) or 3,815 acre (ac) constructed wetland designed and operated for the demonstration of phosphorus reduction from agricultural runoff/drainage. The project is located in south Florida ($26^{\circ} 38' N$, $80^{\circ} 25' W$) at the eastern edge of the Everglades Agricultural Area (Figure 1). The Everglades Agricultural Area is a 240,000 ha (593,000 ac) highly productive irrigation drainage basin with a major production of sugarcane. Ecological changes in the Everglades has been partially attributed to increase in phosphorus concentrations in the inflow waters. Local, state and federal initiatives have been taken to reduce P load from agricultural runoff/drainage. Agricultural runoff/drainage from the agricultural area flows to the south and southeast through four primary canals shown in Figure 1 (Miami, North New River, Hillsboro, West Palm Beach).

A minimum of 25% of the P load in agricultural drainage/runoff is required to be removed at the farm level through the application of various agricultural Best Management Practices (Whalen and Whalen, 1994). Further removal of P is to be achieved through constructed wetland treatment systems known as Stormwater Treatment Areas (STAs). The ENR is a field scale prototype for the large scale STAs. It is built on farm land that was owned by the State of Florida and was previously leased (until 1988) to Knight's Farm for sugarcane and corn production. Originally, the land was part of the Everglades which consisted of wetland prairies, sloughs and stands of custard apple (Davis, 1943). Construction of the ENR started in August 1992 and was completed in October 1993.

Site Description

The ENR Project area is primarily covered by Okeechobee muck soils with very small topographic relief and average ground elevation of 3 meters (m) or 9.84 feet (ft) NGVD; a 1 to 2 m of peat overlies on several meters of carbonate rock (Jammal and Associates, Inc., 1991). To the east, the L-7 levee separates the ENR Project from the Loxahatchee Wildlife Refuge (Water Conservation Area 1 (WCA1)). The northern and western sides of the ENR are encompassed with a seepage canal that separates the ENR levee from agricultural fields. The narrow southern ENR levee runs along the Knight's Farm which currently is not under cultivation. A 12 km (7.5 mile) levee surrounds the ENR and internal levees separate the five interior cells. The Project consists of two parallel treatment trains of two cells each and a buffer (distribution cell). As shown in Figure 2, the upper two cells, Cell 1 and 2, are treatment cells. The lower two cells, Cell 3 and 4, are polishing cells. The eastern treatment train carries water from the Buffer Cell to Cell 1, then to Cell 3 and finally to the outflow pump. The western treatment train carries water from the Buffer Cell to Cell 2, then to Cell 4 and finally to the outflow pump. Average ground elevation and area for each cell is shown in Table 1.

Vegetation Cover and Monitoring

As part of the ENR monitoring plan, temporal and spatial changes of vegetation have been documented through quarterly aerial photography prior to 1995 and semiannually since 1995. Average vegetation cover estimated from four areal photographs (May 15, 1994; October 18, 1994; May 18, 1995; and November 24, 1995), are shown in Table 1. The dominant cover is cattails (41.2%), followed by open water/submerged vegetation (35.7%) and mixed vegetation (23.1%).

SYSTEM HYDRAULICS AND OPERATION

System Hydraulics

West Palm Beach canal water that would otherwise be pumped into the Loxahatchee Wildlife Refuge or WCA 1 via the S5-A Pump Station is partially diverted to the ENR through five culverts and a 3.4 km (2.1 mile) supply canal. Inflow into the constructed wetland, outflow from the constructed wetland, and seepage recycling are performed with lift pumps. The inflow pump station (G250) has six identical pumps with a total capacity of 16.98 cubic meters per second ($m^3 s^{-1}$) or 600 cubic feet per second (cfs). The inflow pumps lift water from the delivery canal into the Buffer Cell. The outflow pump station (G251) has six identical pumps with a total capacity of $12.74 m^3 s^{-1}$ (450 cfs). The outflow pumps lift treated effluent from the ENR into the Loxahatchee Wildlife Refuge. Seepage from the seepage canal is pumped into the Buffer Cell by three identical pumps (G250S) with a total capacity of $5.66 m^3 s^{-1}$ (200 cfs). Pump discharge is computed as a function of head and tail water stages and pump rotations per minute (rpm). Water surface elevation is monitored by automated stage recorders, and staff gages supplement stage readings for operation.

Inter-cell flows are regulated with risers through 16.7 m (55 ft) long and 1.83 m (6 ft) diameter culverts. In the eastern treatment train, water flows from the Buffer Cell into Cell 1 through ten culverts (G252A-J) and from Cell 1 to Cell 3 through ten culverts (G253A-J). Water from Cell 3 is directed to the outflow pump through collection canals. In the western treatment train, water flows from the Buffer Cell into Cell 2 through five culverts (G255A-E) and from Cell 2 to Cell 4 through five culverts (G254A-E). Outflow from Cell 4 moves through five culverts (G256A-E) into a discharge canal that leads to the outflow pump. Water can be recirculated from Cell 2 and Cell 4 via the seepage canal by being released through culverts (G258 and G259, respectively) in the western levee. Water can be transferred from Cell 1 to Cell 4 through culvert G257 when necessary. Flow through culverts is being monitored with Ultrasonic Velocity Meters (UVMs). Currently, the UVMs are in the process of being calibrated. ENR structure locations and monitoring network are shown in Figure 2.

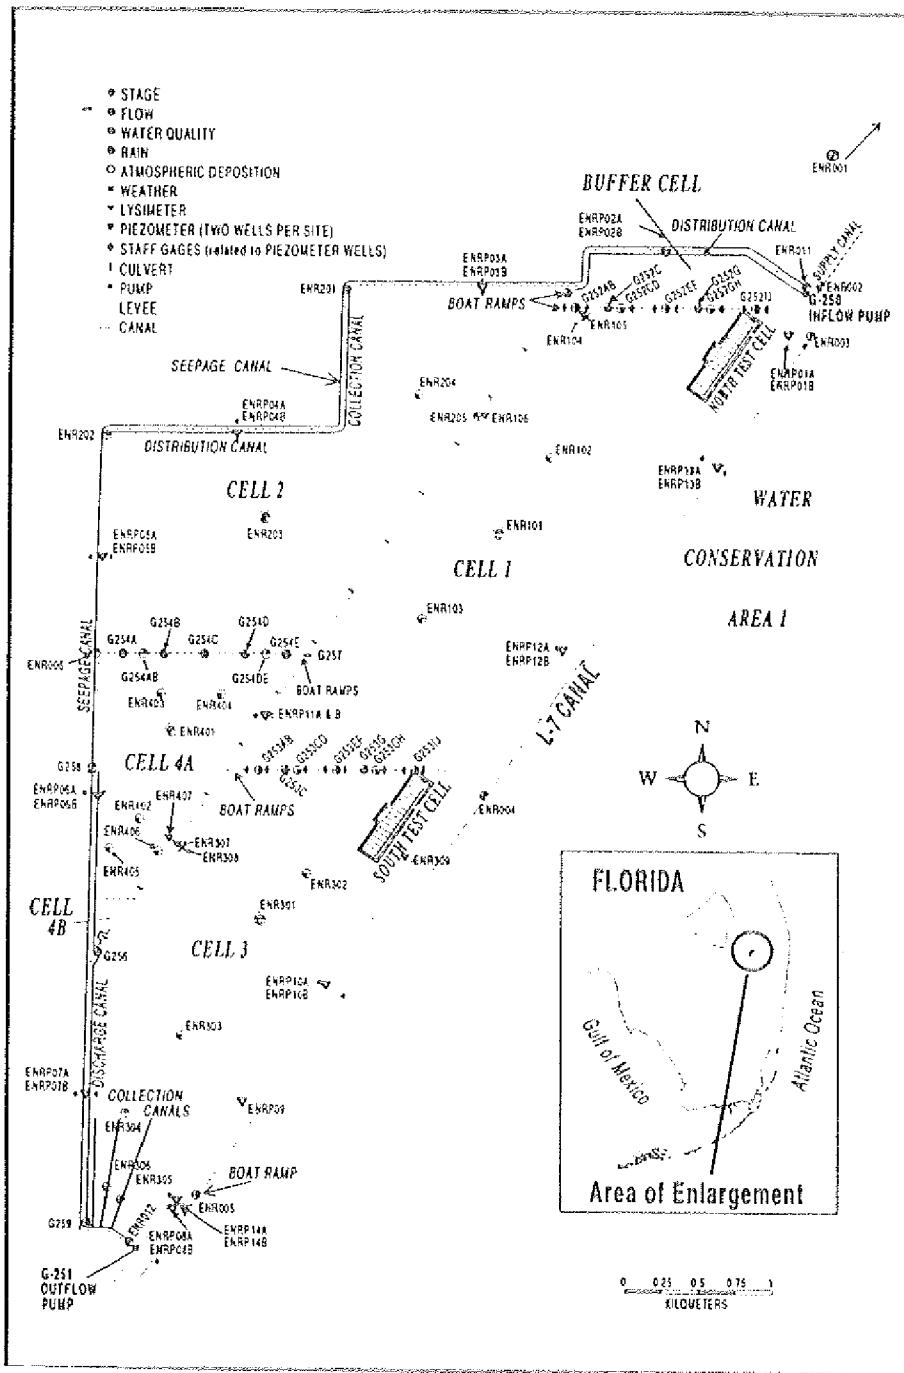

Figure 2. ENR structures and monitoring network

Operation

A preliminary operation plan was developed for the ENR by Guardo and Kosier in 1993. The early start-up and late start-up water depths and stages which were recommended in this plan are presented for each cell in Table 2. The seepage pump started operation in December 1993. Pumping was mainly to recirculate water from the seepage canal and reroute water from cell to cell. The inflow and outflow pumps started operating on August 19, 1994, marking the beginning of full scale operation of the ENR. Inflow and outflow regulations have been a result of many conditions, such as the stage in each Cell, S-5A pump station status, seepage and system capacity tests run in the ENR, construction operations, pump maintenance and others. Detailed information on ENR operations is available in the periodic summary of ENR observations produced by project site managers (ENR Site Observations, Memorandums, SFWMD).

HYDROLOGY AND HYDROLOGIC MONITORING

Rainfall

South Florida has a subtropical climate with relatively high rainfall frequency of occurrence and magnitude. On the average, 34% of the annual rainfall occurs in the dry season (November to May), with the remaining 66% occurring in the wet season (June to October). Mean annual rainfall for the area is 133 centimeters (cm) or 52 inches (in) as reported in Abtew and Khanal (1994). Frontal rainfalls occur in the dry season and have relatively lower spatial variation. Rainfall during the wet season is associated with daily convective and tropical systems which have high spatial variations.

Based on the high variation of summer rainfall observations in the area, a ten-gage rainfall network was established as a pilot network to evaluate the optimum gage density needed for the project area. Network analysis of the first wet season daily rainfall showed that five gages were sufficient for the area (Abtew et al., 1995). As a result, three gages were removed. However, the network could not be reduced to five because three of the gages are associated with the three lysimeters, and four gages (one at the middle of each cell) are part of the monitoring network required by the operating permit. Table 3 lists all the rainfall gaging stations and the corresponding database keys, while Figure 2 shows the gage locations. Areal rainfall on the project site was computed as a Thiessen-weighted average of the previous ten-(and later seven-) gage network. The daily distribution of areal rainfall for the two years of study (August 19, 1994 to August 19, 1996) is depicted by Figure 3. Monthly summary of areal rainfall is shown in Table 4.

Evapotranspiration

Evapotranspiration is measured by three lysimeters installed in Cells 1, 3, and 4. The lysimeters in Cells 1 and 3 are vegetated with cattails and mixed marsh, respectively. The lysimeter in Cell 4 is open water (Figure 2). Two weather stations are located close to the lysimeters for the purpose of estimating ET from weather data. Based on initial observations, the Penman-Monteith model for cattails and mixed-marsh vegetation, and the Penman-Combination equation for shallow open water conditions were calibrated (Abtew and Obeysekera, 1995; Abtew, 1996). Missing daily ET data were filled with respective model-estimated values. For the water budget analysis of the ENR, areal daily ET was computed based on percent type of land cover (Table 1) and the area of each cell (Guardo, 1995). Distribution of daily areal ET from the ENR, for the two years of study (August 19, 1994 to August 19, 1996), is presented in Figure 3, while the monthly summary of areal ET is shown in Table 4.

Flows

Database keys for the flow structures and daily stage gages are listed in Table 5. For the period of study, the inflow pump (G250) and the outflow pump (G251) were in operation 85% and 97.5% of the time, respectively. The seepage return pump (G250S) operated every day of the two-year period. The daily pumping rates of the inflow and outflow pumps are shown in Figure 4a. Flow through culverts G258 and G259 into the seepage canal occurred on 3 days and 133 days, respectively. Figure 4b shows the daily flows through culverts G258 and G259, and seepage recycling pumps (G250S), along with the estimated seepage from L-7 levee flowing through the roadside culverts. The L-7 seepage through the roadside culverts was estimated using a regression equation developed from 42 data points. A relationship was developed between the seepage from L-7 through the roadside culverts and the stage rise in WCA 1 above 4.57 m (15 ft) NGVD, and the difference in stages between WCA 1 and the eastern cells of the ENR (Guardo, 1996). The regression fit had a coefficient of determination (R^2) of 0.93 and a standard error of $0.30 \text{ m}^3 \text{ s}^{-1}$. The equation is given as follows:

$$L-7 \text{ seepage} = 0.217 \Delta WCA^{1.311} * \Delta h^{2.025} \quad (1)$$

where L-7 seepage is in $\text{m}^3 \text{ s}^{-1}$; ΔWCA is the rise in stage in WCA 1 above 4.57 m (15 ft) NGVD and Δh is the difference in stage between WCA 1 and the eastern cells of the ENR. Monthly flow data for the 2-year time period are presented in Table 4.

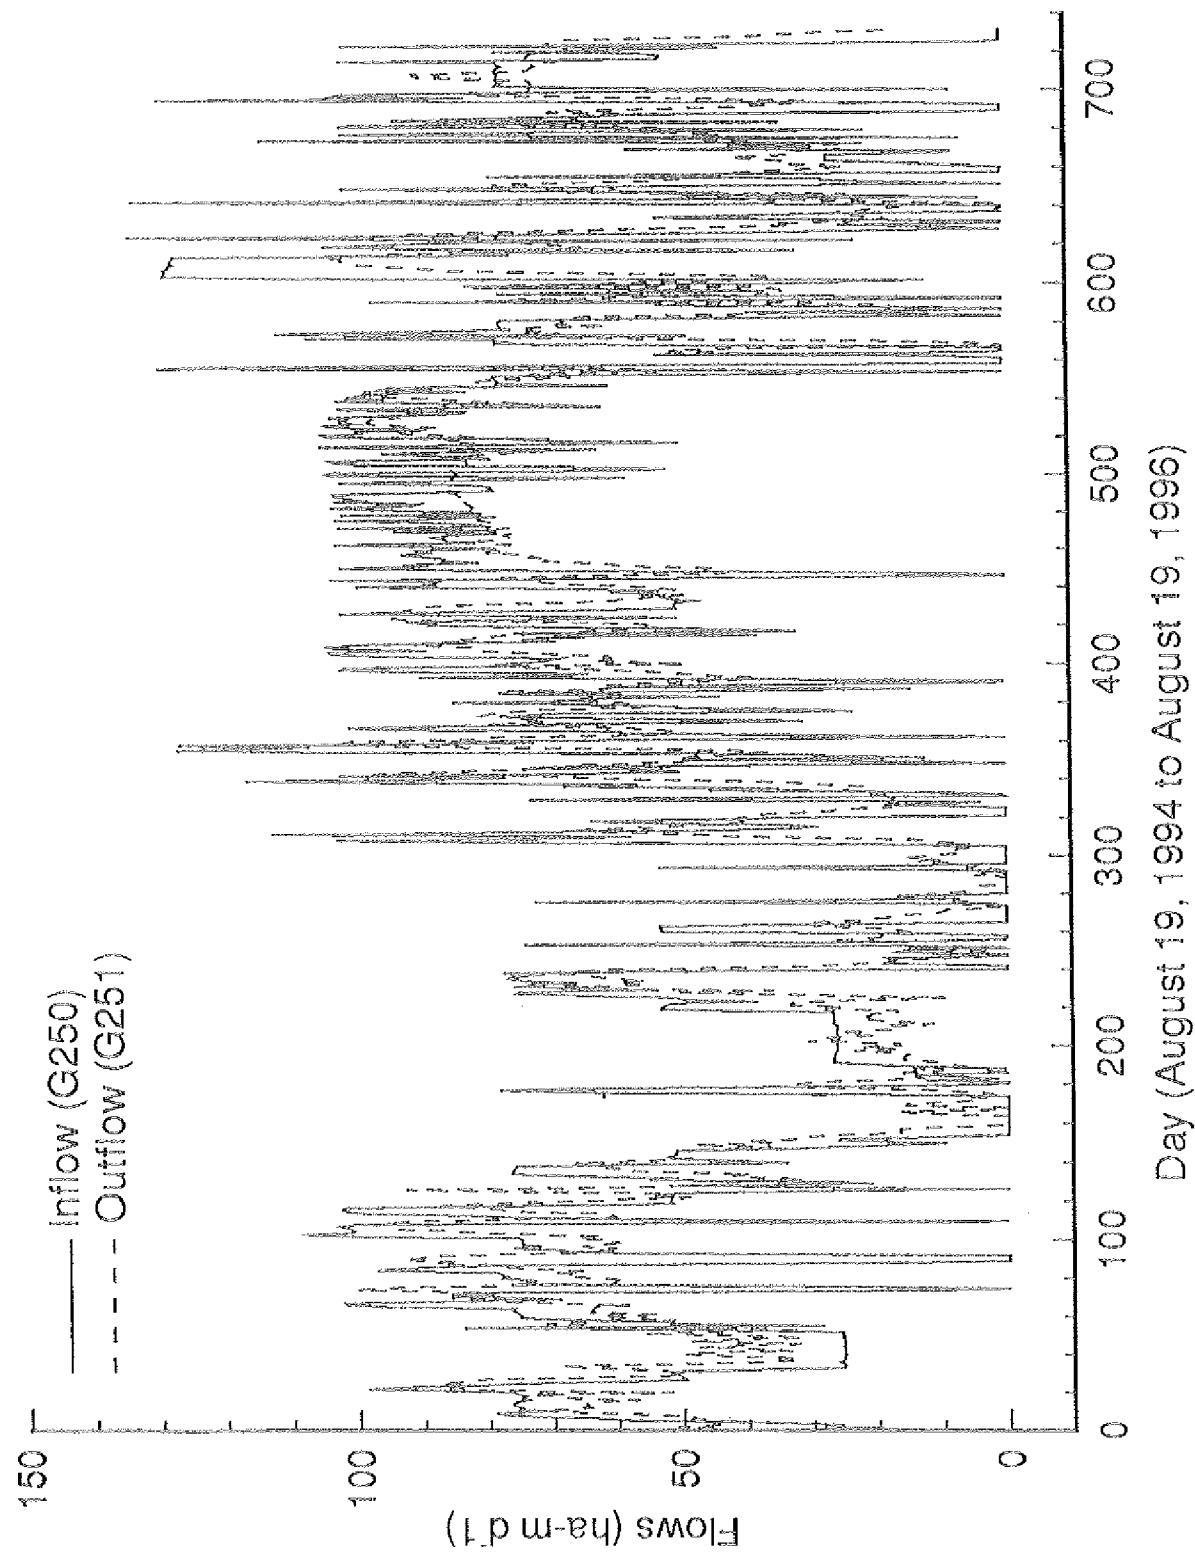

Figure 4a. Daily pumping rates of the inflow and outflow pumps

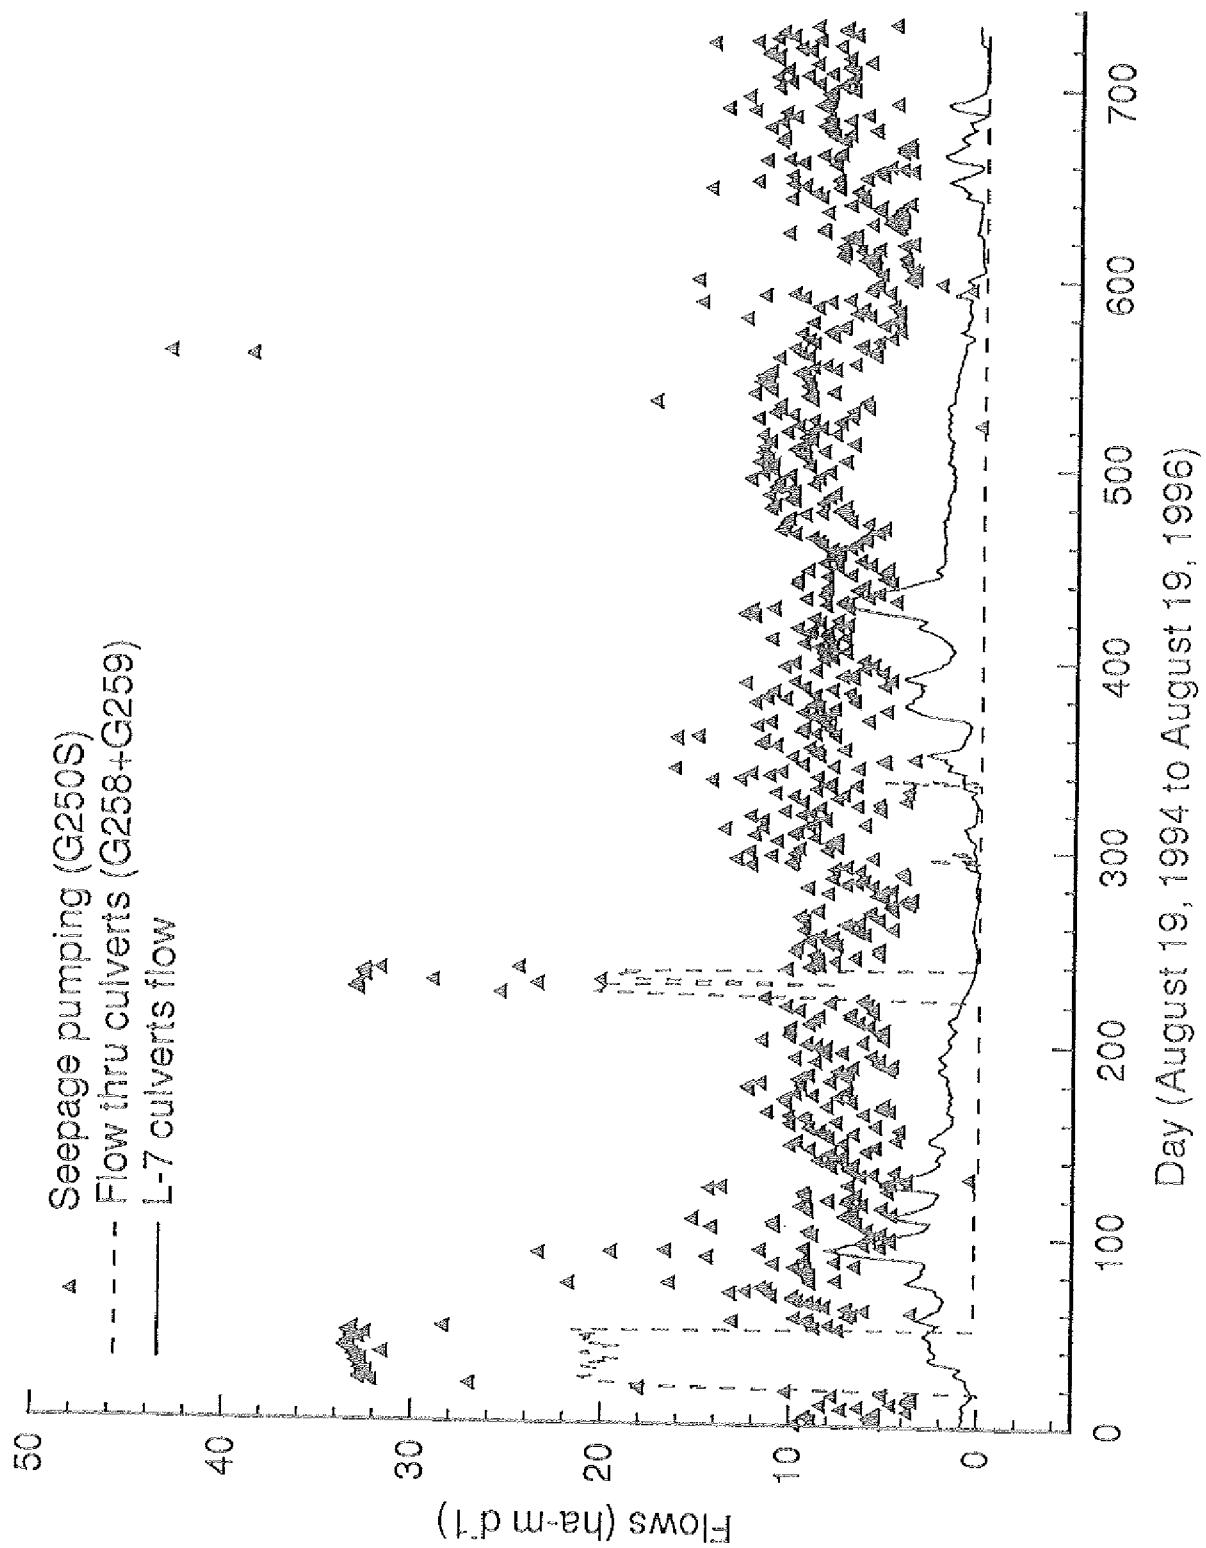

Figure 4b.

Daily pumping rates of the seepage pump, flows through culverts G258 and G259, and seepage flow through L-7 levee roadside seepage collection culverts.

Water Levels

Daily water levels in each cell of the ENR are dependent on rainfall, evapotranspiration, seepage and daily operational decisions. Water levels have been regulated based on water depth, operation status of the S-5A pump station, pump maintenance, and other activities in ENR such as seepage studies and construction operations. The minimum, maximum, and mean of the daily average stage observations for the study period are shown in Table 2. The mean observed stages in each cell are the same as those recommended for the later start-up phase in the preliminary operation plan. Average daily water level observations in the eastern treatment train of the ENR are shown in Figure 5a, while those in the western treatment train are shown in Figure 5b.

WATER BUDGET COMPUTATIONS

Water Balance Model

The schematic hydrologic model for the ENR is depicted in Figure 6. The influent pumped through the G250 pump station accounts for about 86% of the known inflow to the system. The known inflows to the system are the G250 pump station inflows, rainfall, and seepage through the roadside L-7 levee culverts (L-7a). Rainfall accounts for 11% and L-7 seepage through the roadside culverts accounts for 3%. Outflow pumping (G251) accounts for 85% of the known outflows, with evapotranspiration constituting 9% of the total outflows. The unknowns in the system are subsurface inflows and outflows. The schematic model (Figure 6) and the following set of water balance equations represent the hydrologic system of the ENR for water budget analysis purposes.

$$INFLOW - OUTFLOW = \Delta S + \epsilon_T \quad (2)$$

where INFLOW is the amount of water that enters the system from external sources; and OUTFLOW is water that leaves the system boundary and is not recirculated. ΔS is the change in storage in the system during the time interval of interest. Sum of all errors is represented by ϵ_T . Because all inflow and outflow can not be entirely quantified, the following equation is introduced to represent the remainders, errors and unknowns:

$$REMAINDERS = \epsilon_T + UNKNOWNs \quad (3)$$

Figure 6 shows the possible inflows and outflows to and from the ENR system. The seepage canal which encompasses the northern and western sides of the ENR was designed and is operated to capture seepage from the ENR to the neighboring farms.

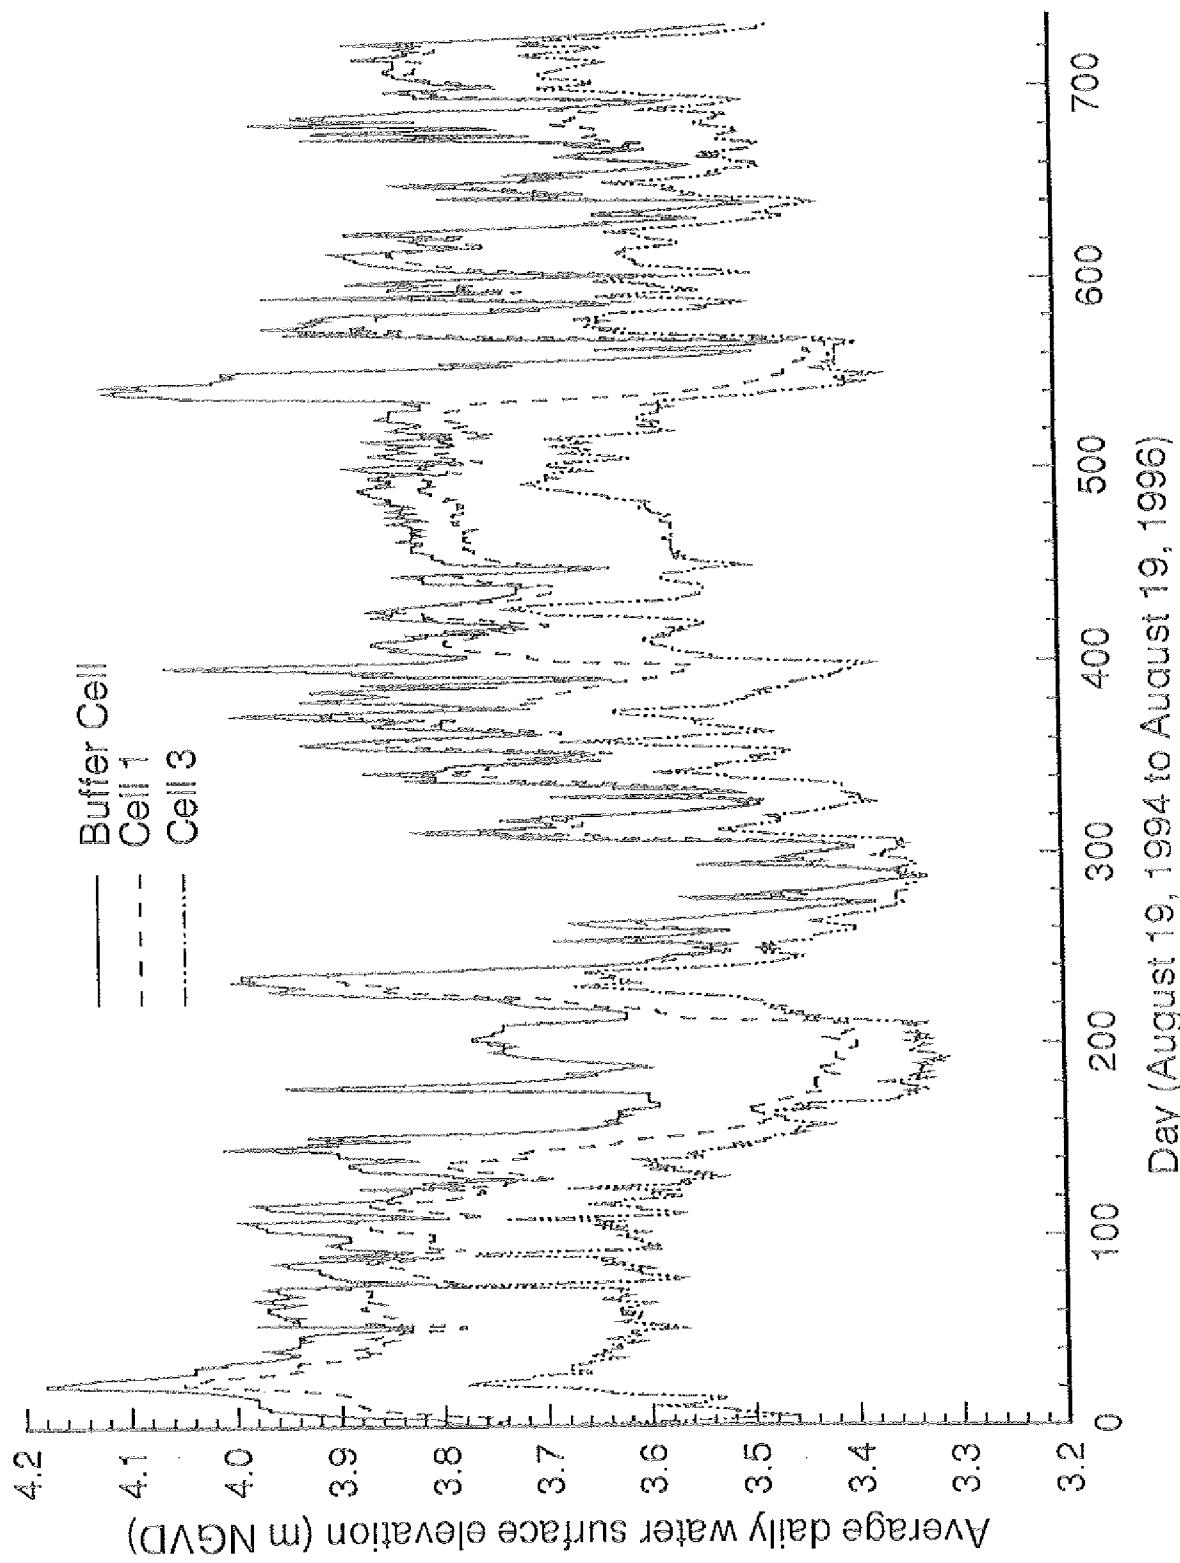

Figure 5a. Daily mean water levels in the eastern cells of the ENR and the Buffer Cell.

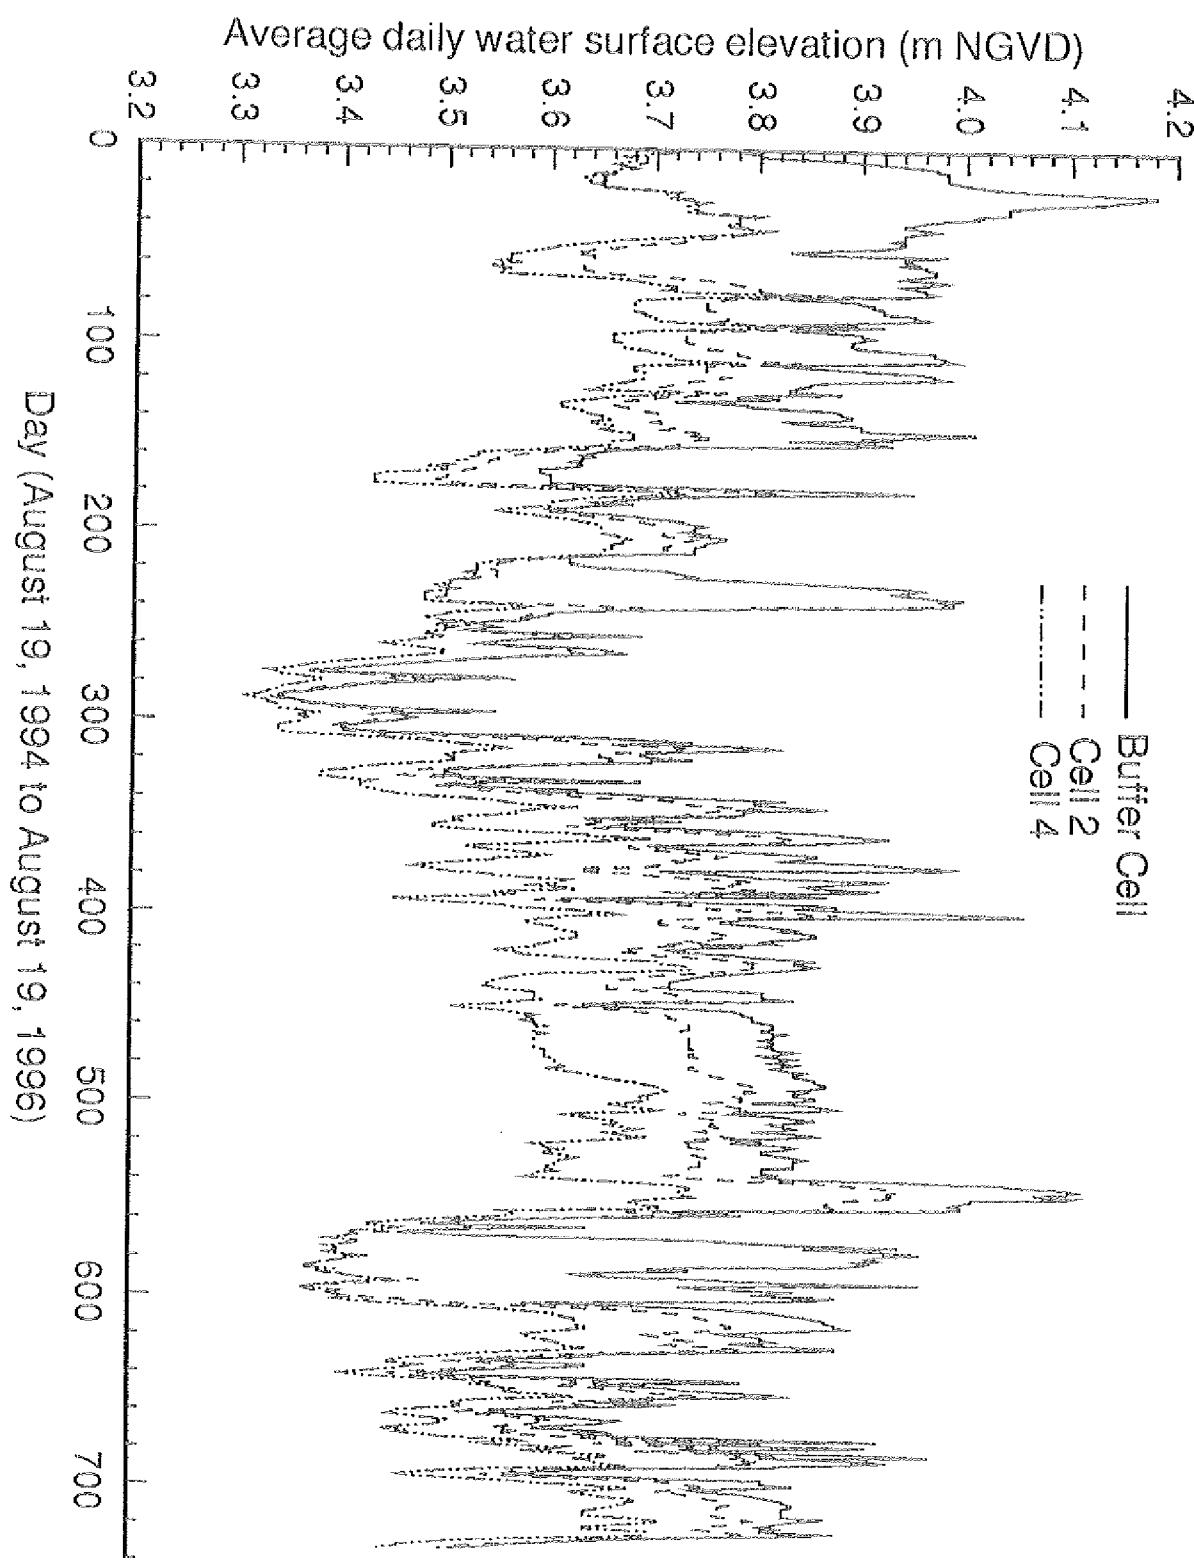

Figure 5b. Daily mean water levels in the western cells of the ENR and the Buffer Cell.

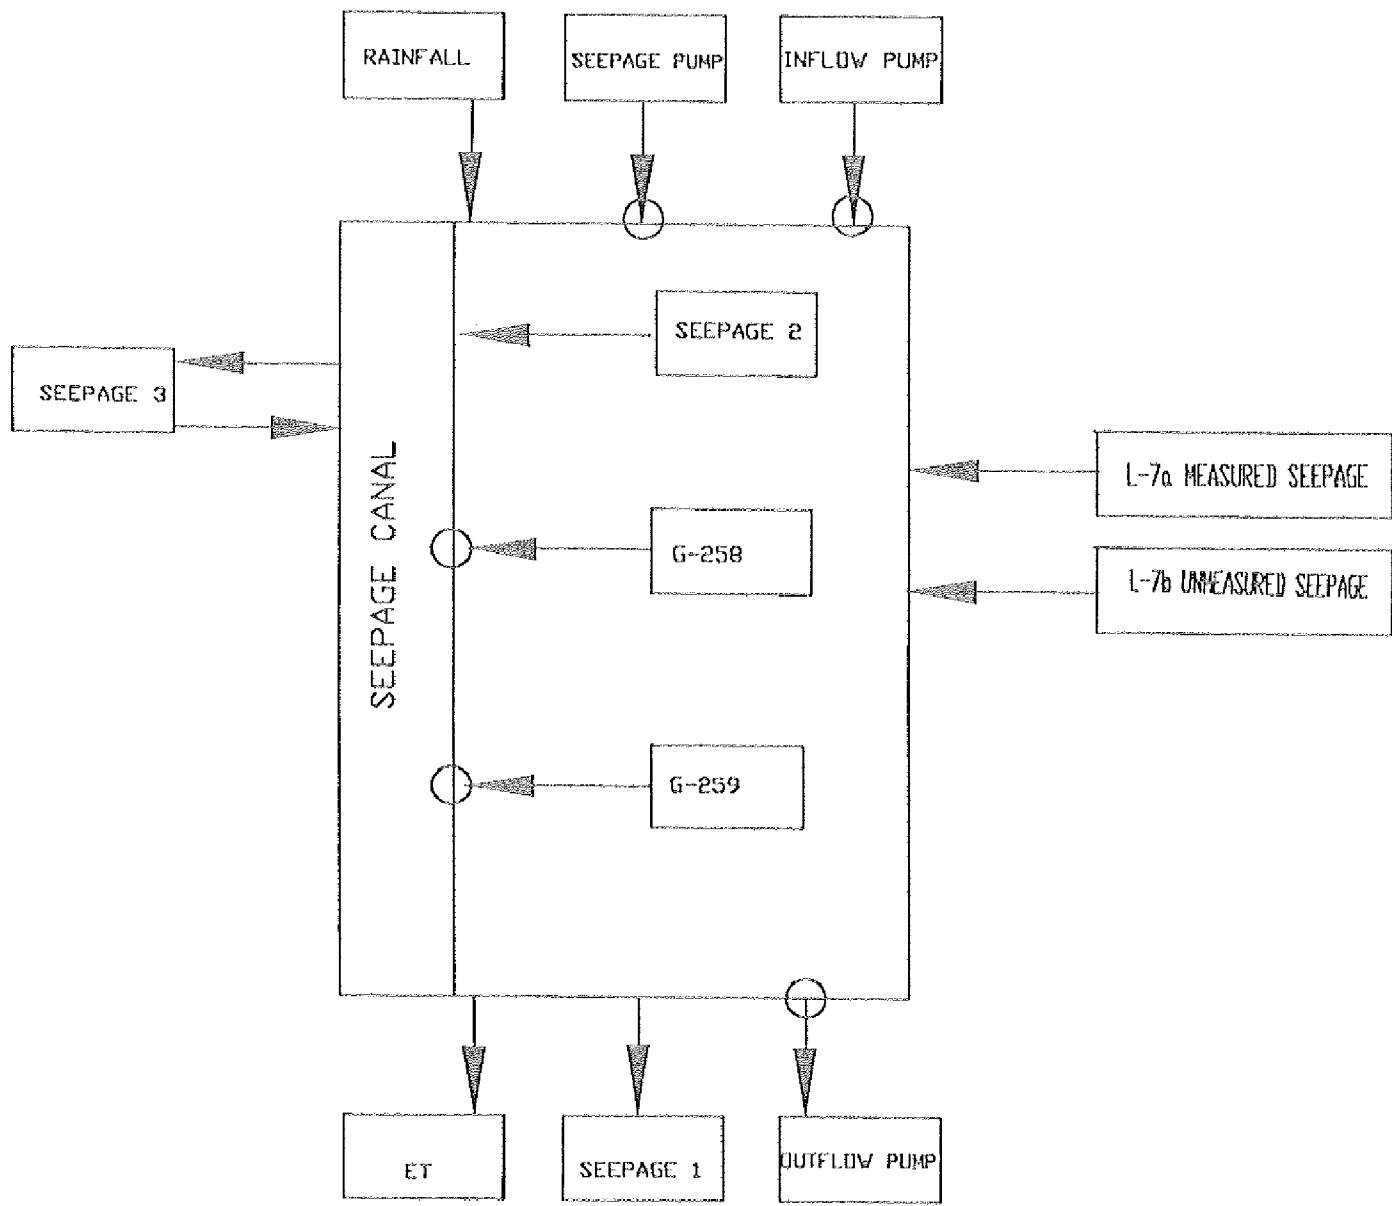

Figure 6. Schematic hydrologic model for the ENR.

When opened, and/or through leakage, G258 and G259 culverts release water into the seepage canal. Seepage through the western and northern ENR levees is represented in the model by SEEPAGE 2, regardless of the magnitude. SEEPAGE 3 represents the two seepage possibilities into or out of the seepage canal from or to the surrounding farms, regardless of the magnitude. SEEPAGE 1 represents the possible seepage loss through the southern ENR levee into the Knight's Farm. The unmeasured seepage flow from WCA 1 into the ENR is represented by L-7b.

In computing the water balance for the ENR, the objectives are to identify quantifiable variables from unquantifiable variables, making reasonable assumptions to reduce the quantity of unknowns as much as possible. Since the purpose of the seepage canal is to recirculate seepage and recycled water, it is assumed that the seepage return pump flows (G250S) are recirculated in the system as designed. This scenario is described or represented in the following equation:

$$S_p = \text{SEEPAGE 2} + G258 + G259 + \epsilon_R \quad (4)$$

where S_p is seepage return pump flows (G250S); SEEPAGE 2 is seepage from ENR to the seepage canal; G258 and G259 are flows through the respective culverts from ENR to the seepage canal; and ϵ_R is error in assumption and all other errors including measurement errors and calibration errors. The error term also includes the net effect of unknown variable SEEPAGE 3 which is the net subsurface flow of water from the seepage canal to the adjacent farms (west and north) or from the farms to the seepage canal. Also, SEEPAGE 1 (seepage through the southern levee of the ENR) and L-7b (subsurface seepage from WCA 1 that is not captured by the roadside culverts) are also unknowns. Equation 2 is expanded as follows.

$$\Delta S = G250 + R + L7a + L7b - G251 - ET - \text{SEEPAGE 1} + \epsilon_R + \epsilon_I + \epsilon_O \quad (5)$$

where ΔS is change in storage in the system; G250 is inflow pump flows; R is rainfall; L7a is seepage flows from WCA 1 through the roadside culverts; L7b is unknown seepage subsurface flow from WCA 1 into the ENR; ET is evapotranspiration losses; SEEPAGE 1 is seepage loss through the southern levee of the ENR; ϵ_R represents errors in accounting for the recirculation water in the system; ϵ_I represents errors in inflow terms; and ϵ_O represents errors in outflow terms. The total error in the system is expressed as follows.

$$\epsilon_T = \epsilon_R + \epsilon_I + \epsilon_O \quad (6)$$

Daily change in storage for the ENR was computed as a sum of storage changes in each of the five cells (Buffer Cell, Cell 1, Cell 2, Cell 3 and Cell 4). Change in storage volume in each cell was computed from the area of the cell and change in stage. Change in stage was computed as the difference between the beginning-of-day and end-of-day average instantaneous stage readings at two or three locations in each cell (Table 5).

The remainders in the computation of daily water balances are the sum of all errors and unknowns in the system. Daily remainders were computed for the two-year study period based on the following equation:

$$REMAINDERS = \epsilon_T - SEEPAGE\ 1 + L7b \quad (7)$$

where ϵ_T is the sum of all errors, SEEPAGE 1 is seepage from the ENR through the southern levee, and L-7b is seepage from WCA 1 into the ENR that is unaccounted for in the water budget.

Discussion

The total inflow through the inflow pump was 39,000 ha-m (316,115 ac-ft) and was almost equivalent to total outflow through the outflow pump which was 38,802 ha-m (314,560 ac-ft). Seepage inflow from the L-7 levee through the roadside culverts was a total of 1,198 ha-m (9,712 ac-ft). Total flow into the seepage canal through culverts G258 and G259 was 892 ha-m (7,231 ac-ft) and the seepage recirculation pump had a total flow of 7,143 ha-m (57,907 ac-ft). Total areal rainfall for the two-year study period was 328.7 cm (129.4 in) and the total areal evapotranspiration was 262.2 cm (103.2 in).

For the two-year study period, the mean daily remainders (errors and unknowns) was -3.8 hectare-meters per day ($ha\cdot m\ d^{-1}$) or -30.8 acre-feet per day ($ac\cdot ft\ d^{-1}$) with the total remainders being -2,781 ha-m (-22,545 ac-ft). The standard variation of the remainders is $12.03\ ha\cdot m\ d^{-1}$ (97 ac-ft d^{-1}) which signifies high variation. Figure 7 depicts the daily remainders distribution. The negative remainder indicates that there is an over all inflow to the system that is not accounted for in the water balance computation. The remainder is 7 % of the inflow or the outflow pumping, or 6% of the sum of all outflows. Summary of the two-year water budget is shown in Table 6. Details of the water balance terms and calculations are shown in the Appendix.

The mean hydraulic loading rate for the two-year period, based on the G250 pump inflow, was 3.45 centimeters per day ($cm\ d^{-1}$) or 1.34 inches per day ($in\ d^{-1}$). The mean hydraulic retention time was computed as the ratio of the mean-estimated volume of the ENR and the total inflow pumping. The mean-estimated volume was computed from the area-weighted (by cell) mean depth of 57.5 cm (22.6 in) and total area of 1544 ha (3,815 ac). The estimated mean hydraulic retention time was 17 days.

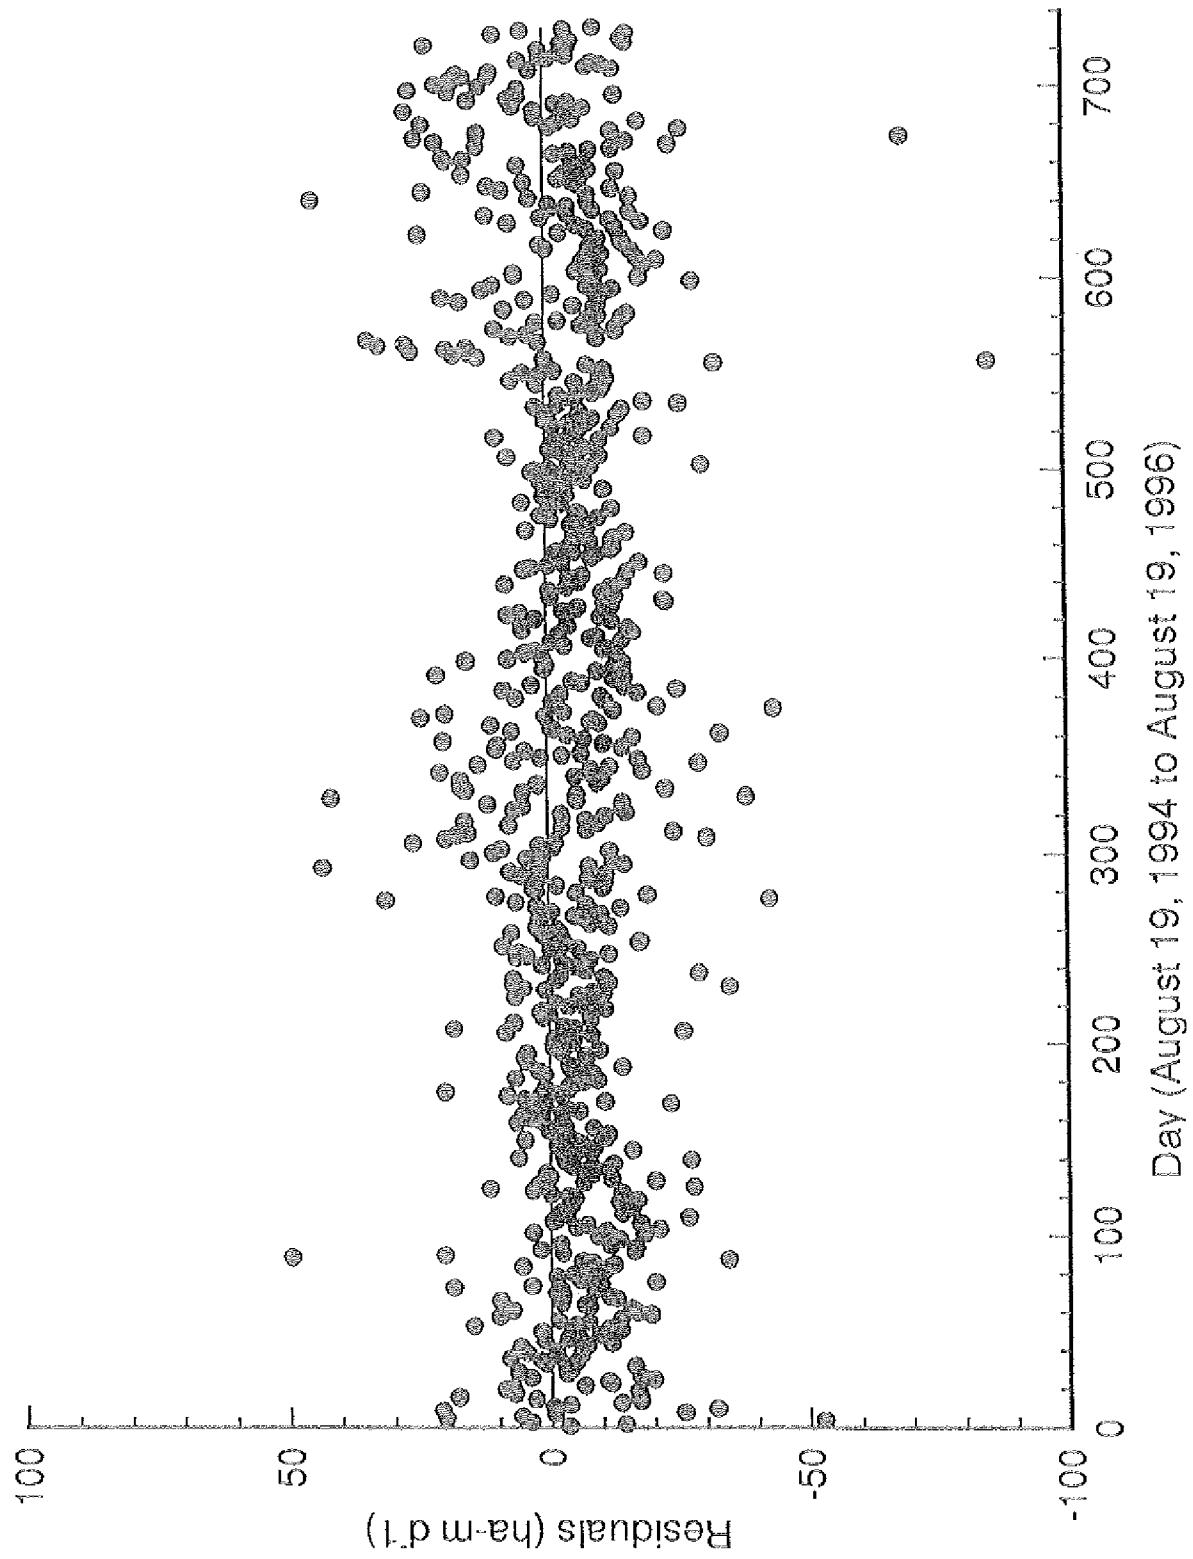

Figure 7. Distribution of daily remainders (errors and unknowns) from the ENR water balance.

Table 6. Summary of the two-year water budget of the ENR

INFLows	ha·m [#]	Percent of Total	OUTFLOWS	ha·m	Percent of Total
Inflow Pump	39,000	86%	Outflow Pump	38,802	85%
Rain	5,068	11%	ET	4,050	9%
17 Culverts (1.7a)	1,198	3%	Remainders	2,781	6%
Total	45,266	100%	Total	45,633	100%
Change in Storage	-363				

ha·m = 8.106 ac·ft

SUMMARY

The ENR is a new system with a relatively short period of hydrologic record. Longer periods of record are more favorable for characterizing the operation and water balance of hydrologic systems. In the ENR, all hydrologic parameters, with the exception of seepage through the system, are well monitored. Since the direction of seepage is not in one direction, the remainders (errors and unknowns) could not be allocated to one variable. Seepage studies and monitoring will refine the water budget for the ENR in the future. Groundwater modeling efforts will help in identifying and quantifying subsurface sources and sinks in the system. Improvement in stage-volume relationships will also increase the accuracy of water balance analysis.
