EXECUTIVE SUMMARY

Water supply plans developed for the Lower East Coast (LEC) Planning Area have identified the Floridan Aquifer System (FAS) as a possible water supply alternative. Based on these plans, the South Florida Water Management District (SFWMD or District) initiated a program of exploratory well construction, aquifer testing, and long-term monitoring to provide data needed to assess the FAS underlying the area. This report documents the results of construction and testing of two new FAS wells by the SFWMD. The wells were constructed within the city of West Palm Beach, just west of the District's headquarters in Palm Beach County, Florida. This site was selected to augment data available from other wells and to provide broad, spatial coverage within the District's LEC Planning Area. The purpose of the drilling and testing program was to assess the subsurface hydrogeologic and water quality properties and to evaluate the water resources potential of the FAS at the site.

The scope of the investigation consisted of constructing and testing two FAS wells. The first well was drilled to a total depth of 2,490 feet below land surface (bls). It was completed as a monitor well into three distinct hydrogeologic zones - an upper zone (PBF-3) between 1,050 and 1,252 feet bls, a middle zone (PBF-4) between 1,360 and 1,510 feet bls and a lower zone (PBF-5) between 2,340 and 2,490 feet bls. The second well (Well PBF-6) was constructed in stages to allow for the performance of pumping tests conducted at intervals corresponding to the open holes of PBF-3 and PBF-4.

The main findings of the construction and testing program are as follows:

- Surficial sediments extended from land surface to a depth of approximately 305 feet bls and the Hawthorn Group (upper confining unit) was found to extend to approximately 915 feet bls.
- Limestone comprising the uppermost FAS was identified at a depth of approximately 915 feet bls based on lithologic and hydrogeologic observations.
- An "upper" producing zone within the uppermost 200 feet of the FAS exhibited a transmissivity of 34,300 square feet per day (ft^2/day). Water sampled from that interval contained a chloride concentration of approximately 2,160 milligrams per liter (mg/L).
- An interval exhibiting somewhat lower hydraulic conductivity was identified between 1,200 and 1,300 feet bls.
- A "middle" producing zone was identified between 1,300 and 1,500 feet bls. This interval demonstrated a transmissivity of approximately 198,500 ft^2/day. Water collected from this zone contained a chloride concentration of 2,090 mg/L.
- The base of the Underground Source of Drinking Water (USDW) was identified by water quality analysis from straddle-packer

tests and geophysical log analysis to occur at approximately 1,800 feet bls at the site.

- A lower zone between 2,300 and 2,400 feet bls within the FAS exhibited a very low hydraulic conductivity (7 ft/day), indicating significant confinement at that depth.
- The unadjusted potentiometric surfaces of the upper and middle monitored FAS intervals (PBF-3 and PBF-4) during the period from April 1997 to March 2001 were approximately +47 feet above the National Geodetic Vertical Datum (NGVD) of 1929. The potentiometric surface of the lower monitored interval (PBF-5) was approximately +9 feet NGVD during the same period.
- Water levels fluctuated an average of 1 to 4 feet in monitored zones over a four-year period of record.
- When adjusted for density, the groundwater gradient between the upper and lower monitored FAS zones was upward.

ACKNOWLEDGEMENTS

The authors gratefully acknowledge the many people that aided in the successful completion of this project. During the well construction and testing, Mr. Robert Tinsely provided guidance and advice to the drilling crews and on-site observers. We would like to thank Mr. Ron Reese, P.G. of the United States Geological Survey (USGS), who reviewed the manuscript and lent technical expertise to the writing of the report.

Appreciation is also extended to the technical and professional staff of the South Florida Water Management District (SFWMD or District) who assisted in the compilation and analysis of data and the production of this report. They include Mr. Michael Bennett, P.G., Mr. Peter Kwiatkowski, P.G., Mr. John Lockwood, P.G., and Mr. Victor T. Mullen.

INTRODUCTION

The South Florida Water Management District (SFWMD or District) constructed two test wells in the greater West Palm Beach area as part of a Floridan Aquifer System (FAS) exploratory drilling program. The wells are located in Lake Lytal Park, just north of Gun Club Road, adjacent to the District headquarters building in Palm Beach County, Florida. The site is located in Section 6 of Township 44 South, Range 43 East, at Latitude 26 degrees, 40' 33" and Longitude 80 degrees north, 06' 11". **Figure 1** presents the locations of all FAS test well sites in the District's Lower East Coast (LEC) exploratory drilling program. The wells were constructed to obtain hydrogeologic and water quality data from the FAS within the LEC Planning Area. This information can be combined with data from other wells in the region to obtain a better understanding of the water resource potential of the FAS. In addition, this information will be used to assist in the conceptual development and calibration of regional ground water flow models. Aquifer storage and recovery (ASR) wells have been proposed by the United States Army Corps of Engineers (USACE) and the District in the Comprehensive Everglades Restoration Plan (CERP) for this initiative. Local FAS information obtained from these wells will be particularly useful.

A monitor well was first completed to a total depth of 2,490 feet below land surface (bls). The well taps three zones within the FAS - an upper zone (PBF-3, from 1,050 to 1,252 feet bls), a middle zone (PBF-4, from 1,360 to 1,510 feet bls) and a lower zone (PBF-5, from 2,340 to 2,490 feet bls). Well PBF-6 was later completed as a dual-zone test-production well. The purpose of Well PBF-6 was to facilitate performance of two aquifer performance tests (APTs) which were conducted to estimate hydraulic properties and water quality within different portions of the FAS. After the pumping tests were performed, Well PBF-6 was completed with an open hole between 1,360 and 1,510 feet bls.

District staff served as overall project manager during this investigation, preparing the well designs and technical specifications, and performing construction oversight of the drilling contractor. RST Partnership, Inc. (RST), of Fort Myers, Florida was selected as the low-bid contractor to construct the wells. A District drilling contract (C-7660) was executed in December 1995 and a Notice to Proceed was issued in May 1996. Construction began in June 1996 and was completed in April 1997. The contract included drilling, construction, and testing of Well PBF-3-4-5, and PBF-6, and installation of associated wellhead piping and appurtenances.

CONSTRUCTION DETAILS

Floridan Aquifer System wells were installed on the western edge of Lake Lytal Park, located just west of the District headquarters near the intersection of Kirk Road and the C-51 Canal. The locations of the wells relative to these landmarks are shown in **Figure 2**. The drilling schedule and well casing setting depths for each of the wells were designed to conform to the hydrogeologic features observed at the site. Data collected during construction and testing of the wells resulted in the interpretation of lithology, geophysical properties, water quality, water levels, transmissivity, storage and leakance coefficients

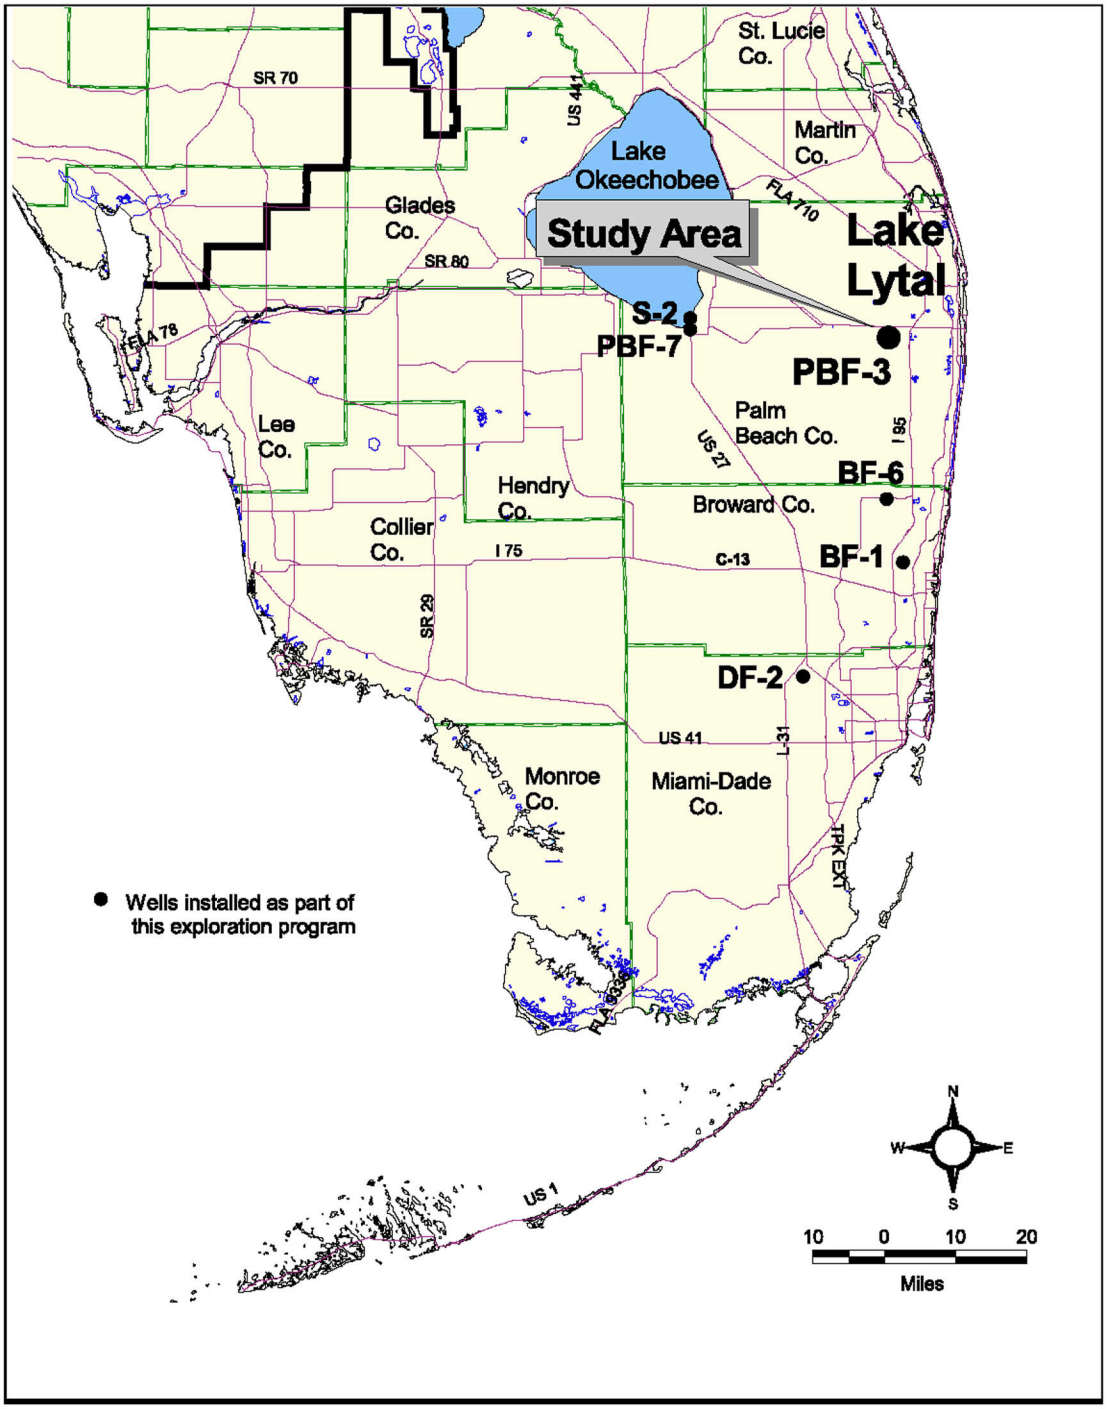

Figure 1. Lower East Coast Exploratory Drilling Program Site Locations.

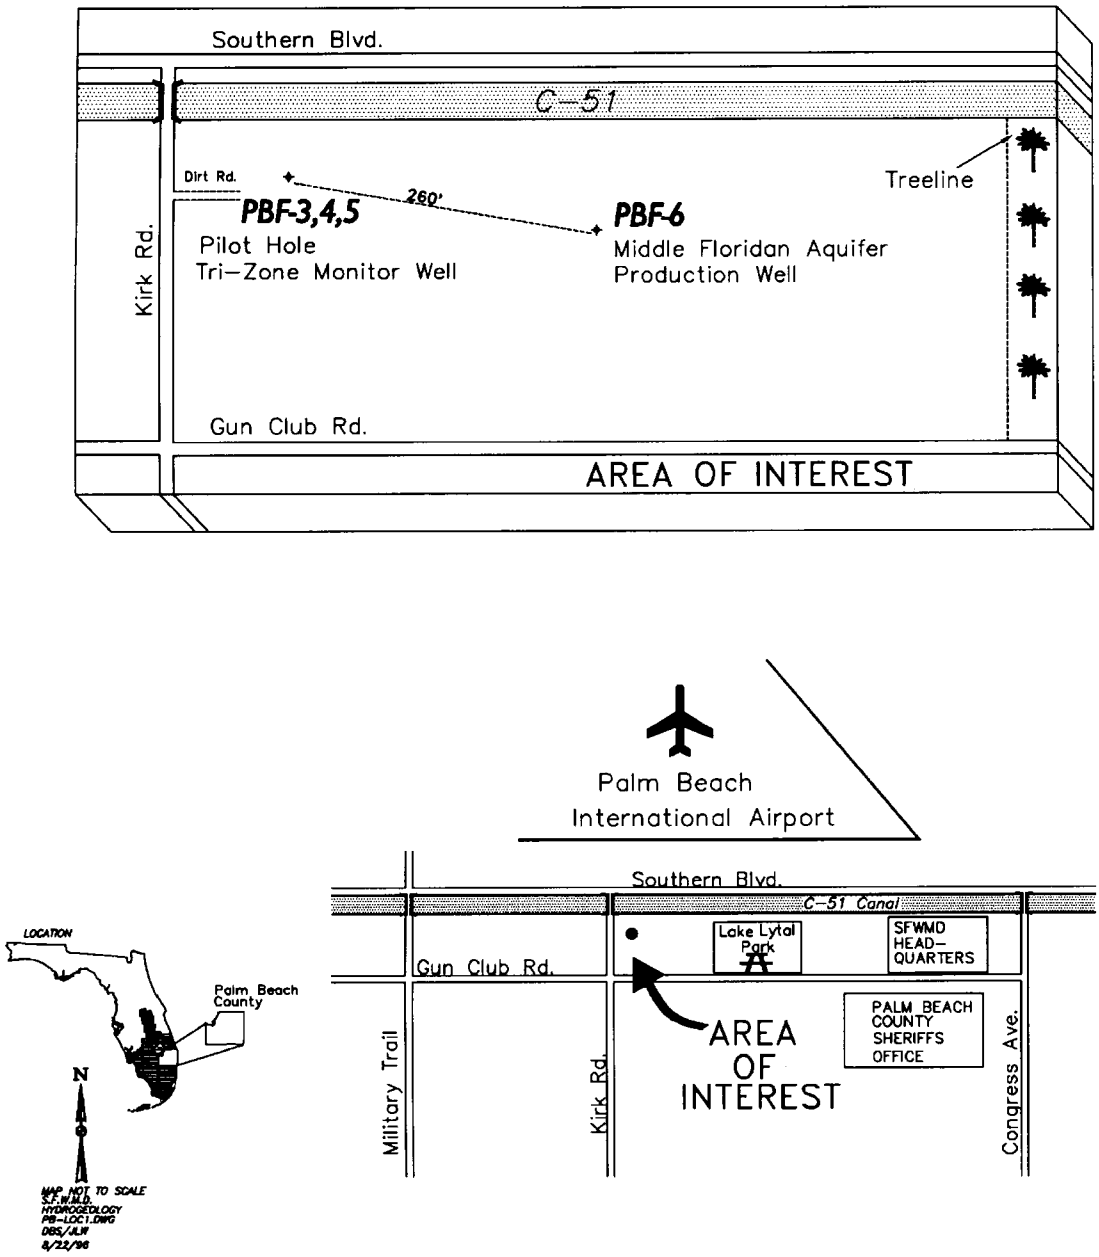

Figure 2. Project Location Map.

corresponding to the producing zones within the FAS. The data were obtained from collection and description of drill cuttings, borehole geophysical logs, straddle-packer pumping tests, and two APTs.

Well construction began in April 1995 with the rig positioned at the location of Well PBF-6, within the interior of the park. Intermediate casing was installed to a depth of 885 feet bls; however, reverse-air drilling failed to advance through silts and fine sands encountered between the depths of 890 to 960 feet bls. Drilling operations at Well PBF-6 were terminated and the rig was moved 260 feet west, closer to Kirk Road. A tri-zone monitor well (Well PBF-3-4-5) was then constructed and tested between August 1995 and March 1996. Once Well PBF-3-4-5 was completed, the rig was moved back to Well PBF-6, which was completed between April 1996 and July 1996.

Monitor Well Construction Summary

Construction of the tri-zone monitor well (PBF-3-4-5) was initiated in August 1995 and completed in March 1996. This well was drilled and tested to a total depth of 2,487 feet bls. The names corresponding to the upper, middle and deep FAS monitor zones were PBF-3-4-5, respectively. The upper monitor zone (PBF-3) was completed from 1,050 to 1,252 feet bls; the middle monitor zone (PBF-4) from 1,360 to 1,510 feet bls; and the lower monitor zone (PBF-5) was completed from 2,340 to 2,490 feet bls.

Construction included the installation of five concentric casings (24-, 18-, 12-, 7-, and 2-inch diameters). A 30-inch diameter hole was drilled initially, followed by the placement of 24-inch diameter pit casing to a depth of 40 feet bls. A nominal 12-inch diameter pilot hole was then drilled using the mud rotary method inside the pit casing to the top of the Hawthorn Group sediments to a total depth of 320 feet bls. The pilot hole then was reamed to a nominal 24-inch diameter and a caliper log was conducted. An 18-inch diameter steel casing was subsequently cemented in place to a depth of 320 feet bls. The casing was pressure grouted with neat cement containing 12 percent bentonite. Pilot hole drilling resumed using the mud-rotary method to a depth of 1,084 feet bls. Geophysical logs including the long and short-normal resistivity (LSN), gamma ray, temperature, fluid resistivity, spontaneous potential (SP), and caliper were then conducted. A casing setting depth of 1,050 feet bls was selected for the 12-inch diameter casing, based upon the presence of a hard, clean, competent limestone encountered at this depth.

The cuttings descriptions indicated that a limestone-bearing interval began at a depth of approximately 850 feet bls. This interval could represent a portion of the Arcadia Formation, positioned near the base of the Hawthorn Group. A copy of the lithologic description for Well PBF-3-4-5 provided by the Florida Geological Survey (FGS) is contained in **Appendix A**. The attenuated gamma ray log response indicated that the top of hard, clean, uniform limestone representing the upper FAS was present at a depth of 1,060 feet bls. This information was used to select the setting depth of 1,050 feet bls for 12-inch diameter casing.

The pilot hole was reamed to a nominal 18-inch diameter to a depth of 1,050 feet bls. The 12-inch diameter casing was installed to a depth of 1,050 feet bls and cemented to land surface. Once the cement cured, an 8-inch diameter pilot hole was advanced to a depth of 1,650 feet bls using the reverse-air drilling method. The drill pipe then was removed and the borehole (from 1,050 to 1,650 feet bls) was developed until discharge water was clear of sediments. Geophysical logging operations were conducted on December 18, 1995 by RST using Century Geophysics Inc. logging equipment, and included the following logs: gamma ray, LSN, SP, caliper, flowmeter, temperature, and fluid resistivity. The geophysical log traces are contained in **Appendix B**. Following the geophysical logging, Straddle-Packer Test No. 1 was conducted on the open-hole interval between 1,246 and 1,304 feet bls. The results of the straddle-packer testing are discussed in subsequent sections.

Following Straddle-Packer Test No. 1, 8-inch diameter pilot-hole drilling resumed using the reverse-air drilling method to a total depth of 2,490 feet. The drill pipe was again removed and geophysical logs were conducted between 1,050 feet bls and total depth: 2,490 feet bls. Logs included the natural gamma ray, LSN, SP, caliper, temperature, flowmeter, fluid resistivity, and borehole video survey. Results of these logs were used to identify permeable zones for additional packer testing. The intervals between 2,340 and 2,485 feet bls (Straddle-Packer Test No. 2), between 1,360 and 1,500 feet bls (Straddle-Packer Test No. 3), and between 1,050 and 1,190 feet bls (Straddle-Packer Test No. 4) then were tested. When the packer tests were complete, the drill pipe was withdrawn and the borehole was air-developed.

The straddle packer test results and geophysical logs were combined with other borehole data to establish the setting depths for both the 7- and 2-inch diameter casings. A nominal 12-inch diameter bit was used to ream the pilot hole to a depth of 1,360 feet bls. A caliper log was then conducted and a 7-inch diameter Schedule 80 polyvinyl chloride (PVC) casing was installed to a depth of 1,360 feet bls. The annular space around the lower-most 50 feet of the casing was pressure-grouted with neat cement. The remaining annular space to 1,252 feet bls then was cemented via the tremie method, resulting in creation of an upper monitor zone (PBF-3) between 1,050 and 1,252 feet bls. After the cement cured, the monitor zone was air-developed until discharge water was clear of suspended solids.

A nominal 6-inch diameter bit was then run through the 7-inch diameter PVC casing to clean out the borehole between 1,360 and 2,390 feet bls. Pea gravel was poured through the 7-inch casing to partially backfill the borehole between 2,390 and 2,340 feet bls. A caliper log was then conducted. The 2-inch diameter fiberglass reinforced polyethylene (FRP) final tubing was then installed to 2,340 feet bls and pressure grouted between 2,340 and 1,600 feet bls. The annular space between 1,600 feet and 1,510 feet bls was subsequently cemented via the tremie method, creating a middle monitor zone (PBF-4) between 1,360 and 1,510 feet bls. After the cement cured, it was tagged with a wire-line to verify depth. The open hole below the base of the final tubing was then cleaned and air-developed until discharge water was clear of suspended solids. The lower zone (PBF-5) was completed between 2,340 and 2,490 feet bls.

The wellhead was subsequently equipped with ports for measurement of potentiometric heads and water quality sampling of all three zones. The elevation of the monitoring ports and land surface were surveyed by the District after the rig moved off site. **Table 1** presents the elevation information from the surveyed wellhead. A reinforced concrete pad was then built around the wellhead and a chain-link fence with locking hinged gate was installed around the pad. As-built drawings for the wells completed during this project are shown in **Figure 3**. A photograph of the completed wellhead of PBF-3-4-5 is presented on **Figure 4**.

Table 1. Surveyed Wellhead Elevations of Well PBF-3, PBF-4, and PBF-5.

Measuring Point	Wellhead Elevation (in feet above NGVD, 1929)	
	1996 (old)	2001 (new)
Land Surface	+21.53	+21.53
PBF-3	+23.13	+24.63
PBF-4	+24.63	+24.28
PBF-5	+24.31	+23.13

Production Well Construction Summary

Production Well PBF-6 was designed and constructed as a dual-zone test-production well. This configuration allowed for performance of aquifer performance pumping tests at depths corresponding to the monitor zones of Wells PBF-3 and PBF-4. The upper test zone of Well PBF-6 was completed between 1,050 and 1,252 feet bls. The middle zone was completed between 1,360 feet and 1,510 feet bls.

Construction began in May 1995 when the 24-inch-diameter pit casing was grouted in place to an approximate depth of 40 feet bls. A nominal 8-inch diameter hole then was drilled by the mud-rotary method to a depth of 320 feet bls followed by geophysical logging. The borehole was then reamed to a nominal 24-inch diameter bit to 240 feet bls. An 18-inch diameter steel surface casing then was installed to 240 feet bls and pressure grouted with neat cement to land surface.

After the cement cured, a nominal 8-inch diameter pilot hole was drilled inside the 18-inch casing using the mud-rotary method to a depth of 885 feet bls, where competent limestone was encountered. The drill rods were removed from the well and geophysical logs were conducted. At that time, it was thought that the upper FAS was penetrated at 885 feet bls based on the cuttings and geophysical logs. This later proved to be a limestone "stringer" within the lowermost Hawthorn Group.

Once logged, the open-hole between 240 and 892 feet bls was reamed using a nominal 18-inch diameter bit. A caliper log was conducted, then a 12-inch diameter steel casing was pressure grouted with neat cement from 892 feet bls to land surface. Reverse-air drilling then commenced; however, failed to advance the borehole through unconsolidated silts and fine sands encountered between 890 to 960 feet bls. Drilling operations were then terminated and the rig was moved 260 feet west, to the cluster monitor well site in August 1995.

The drill rig returned to Well PBF-6 site in April 1996. The open-hole was advanced using a nominal 12-inch diameter bit and mud circulation to a depth of 1,050 feet bls. A 10-inch-diameter steel casing was then pressure grouted using a 12 percent bentonite-cement slurry from 750 to 1,050 feet bls. After the cement cured, the borehole was drilled with a 10-inch diameter bit via the reverse-air method to a depth of 1,250 feet bls. This depth was selected for testing since it was near the base of the uppermost producing zone within the upper FAS. The open-hole interval between 1,050 and 1,250 feet bls then was developed until discharge was clear of particulates. On April 30, 1996, APT No. 1 was conducted over the open-hole interval from 1,050 to 1,250 feet bls.

Following APT No. 1, a nominal 10-inch diameter borehole was drilled with the closed-circulation reverse-air method to a depth of 1,360 feet bls. This depth corresponded to the middle FAS zone observed in Well PBF-6. An 8-inch diameter steel casing was installed between 650 and 1,360 feet bls. This final casing was pressure-grouted with neat cement containing 12 percent bentonite from 650 to 1,360 feet bls. After the cement cured, the borehole was advanced with an 8-inch diameter drill bit using the reverse-air, closed-circulation drilling method to a total depth of 1,510 feet bls. The drill pipe was then

withdrawn and the open hole was developed until discharge water was clear of particulates in preparation for APT No. 2.

On July 1, 1996, APT No. 2 was performed on the interval from 1,360 to 1,510 feet bls. Once APT No. 2 was complete, a 12-inch diameter iron yolk valve was installed at the wellhead and equipped with a monitoring port for measurement of piezometric heads and water quality sampling. The wellhead was completed with a reinforced concrete pad surrounded by a locked, chain-link fence. The contractor then restored the wellsite and demobilized in August 1996. A photograph of the completed wellhead is presented on **Figure 5**.

Figure 5. Well PBF-6 Completed Wellhead.

FORMATION TESTING PROGRAM

Cuttings Collection During Drilling

Lithologic samples (well cuttings) were circulated to land surface while drilling the pilot hole to the total depth of both wells constructed during this project. The mud-rotary drilling method was used from land surface to a depth of approximately 1,100 feet bls, below which the reverse-air method was utilized. During mud-rotary drilling, formation cuttings were circulated from the bottom of the drilled hole to land surface. The cuttings were collected at 10-foot intervals in a sieve that was suspended at the end of the mud discharge line. Cuttings then were rinsed with fresh water and described by the site geologist. The cuttings were compared with other information collected from the drilling process, such as penetration rate and wellhead flow rates to characterize of the penetrated geologic formations.

The pilot hole below 1,100 feet bls was drilled using the reverse-air drilling method. The drilled cuttings were collected at ten-foot intervals and/or at formation changes. Cuttings were described by the site geologist noting lithologic type, color, grain size, sorting, accessory minerals, fossils, etc. Observations of bit penetration rate, changes in flow rate observed at the discharge line, and miscellaneous drilling information, also were recorded.

After they were described, cuttings were bagged and hung to dry. At the end of each week, the cuttings were transported back to the District warehouse located in West Palm Beach. After processing, the cuttings were transferred to the FGS in Tallahassee, for detailed description. The detailed FGS lithologic description for Well PBF-3 (FGS Well No.W-17397) is available in the FGS geologic database, and is presented in **Appendix A**.

Geophysical Logging

Geophysical logs were conducted in the pilot holes of Wells PBF-3 and PBF-6 to correlate with formation samples collected during drilling, identify lithologic and formation boundaries, correlate formation boundaries between wells, and obtain data pertinent to the underlying stratigraphic formations and aquifers. These data then were used in the selection of the optimum straddle-packer test intervals and for the determination of casing setting depths. Geophysical logs were run by the drilling contractor (RST) using Century Geophysics logging equipment. A list of the geophysical logs performed on Well PBF-3 and PBF-6 is presented on **Table 2**.

The uses and interpretations of each of the logs is described as follows:

Caliper Log: measures the diameter of the borehole. This log is useful in identifying wash-outs, fractures and competency (mechanical strength) of the strata.

Table 2. Geophysical Log Summary.

Date	Geophysical Log Type	Casing Depth (feet bls)	Total Log Depth (feet bls)
Well PBF-3-4-5			
1995	Caliper	318	1,082
1995	Natural Gamma, LSN, SP, Temperature, Fluid Resistivity	318	1,082
12/18/95	Natural Gamma, LSN, SP, Temperature, Fluid Resistivity	1,055	1,656
12/18/95	Caliper, Flowmeter, Borehole Video	1,055	1,656
02/01/96	Caliper, Natural Gamma, LSN, SP, Temperature, Fluid Resistivity	1,597	2,489
02/01/96	Caliper, Flowmeter	1,597	2,460
Well PBF-6			
03/31/95	Natural Gamma, LSN, SP, Temperature, Fluid Resistivity	236	885
05/12/95	Caliper	236	885

Note: "LSN" denotes long and short Normal Resistivity. "SP" denotes Spontaneous Potential.

Gamma Ray Log: measures the natural gamma radiation produced by the rock, which is normally a function of the clay or phosphate content (in South Florida).

Spontaneous Potential (SP) Log: measures the natural potential fields that are created between borehole fluids and the ambient formation materials. These logs are used primarily for correlation purposes.

LSN/Electric Log: measures the electrical properties of the formation. The resistivity of the formation is affected by lithology, porosity, and water quality. These logs are comprised of "shallow" and "deep"-penetrating sondes that investigate at various distances from the borehole into the formation.

Temperature Log: measures the temperature of the borehole fluid and provides information about the movement of fluids within drilled boreholes. It is also used to determine the elevation of emplaced cement during casing installation.

Fluid Resistivity Log: provides a measurement of the borehole fluid resistivity, which is a general indicator of the chemical quality of the water within the borehole.

Borehole Video Log: provides a visual image of the borehole and casing.

Flowmeter Log: measures the relative contribution of water from various depth intervals of the drilled borehole. Useful in determining flow zones and confining units within the penetrated strata.

The majority of the Well PBF-3-4-5 borehole (between 1,050 and 2,460 feet bls) was enlarged to a diameter that exceeded 18 inches. This was due primarily to the "washing out" of the hole during reverse-air drilling. This large diameter borehole reduces the accuracy of the LSN-resistivity geophysical logs. Portions of the borehole that were not enlarged were intervals consisting of well-indurated and crystalline limestones and dolostones. In these intervals, the tool pads functioned within their design limits, and came in contact with the borehole wall, resulting in good geophysical log data. Geophysical log traces for the pilot-hole of Well PBF-3 are presented in **Appendix B**. A complete set of geophysical logs are on file at the District headquarters in West Palm Beach, Florida.

Water Sampling During Drilling

Flowing wellhead water samples were collected during reverse-air drilling at the end of each drill rod (usually at 30-foot intervals). Field water quality parameters including pH, specific conductance, and temperature were measured on these samples using a Hydrolab multi-parameter probe. Chloride concentrations also were determined using a Hach field titration kit. These test results were then recorded as part of the on-site drilling log.

Reverse-air drilling affords the opportunity to collect water samples from near the drill bit as it penetrates the aquifer system; however, these samples do not always accurately reflect the depth-specific water quality. Interpretation of water quality changes within the FAS must, therefore, be made using all available pilot-hole information, including the geophysical logs and confirmed using the water quality results from actual samples obtained during straddle-packer and APTs.

Straddle-Packer Pumping Tests

Four separate straddle-packer pumping tests were conducted on Well PBF-3 within the pilot hole between 1,050 to 2,485 feet bls. The purpose of packer testing was to identify hydraulic properties and confirm the water quality of discrete intervals within the pilot hole. Tested intervals were selected using all available field information including lithologic cuttings, reverse-air water sampling results, water-level observations and geophysical log data.

During a straddle-packer pumping test, two inflatable packers were attached to a perforated portion of drill pipe and lowered into the well to a preselected depth. Once the inflatable elements were positioned properly, they were inflated with a high-pressure nitrogen line from the surface. Water then entered the perforated portion of the drill pipe from within the isolated interval. A 4-inch diameter submersible pump then was lowered approximately 90 feet down into the pipe assembly. This pump had a maximum sustained pumping capacity of approximately 260 gallons per minute (gpm). A discharge hose

conveyed water from the pump through an in-line flowmeter and into storage tanks at the surface. Pressure transducers were then installed in the drill pipe below the static water level and remained submerged for the duration of the pumping tests. The transducer cables were connected to In-Situ Inc. data-loggers to record water levels as a function of time. Water levels also were manually recorded using a water level sensor for all transducers prior to pumping.

The submersible pump was energized to begin each test, and water level data were recorded. The pumped flow rate, as measured by the in-line flowmeter and manometer (recorded with pressure transducer), also was recorded manually to ensure that a constant pumping rate was maintained during the test. After three borehole volumes were purged from the pumped well, water samples were collected from the discharge line. These samples were collected using all applicable District Quality Assurance/Quality Control (QA/QC) standards and transported to the District lab for analysis. Major ions were analyzed by the District lab for all water samples.

After a steady-state water level was established and maintained for a period of 1 to 4 hours, the pump was shut down and a recovery period commenced. During the recovery period, water levels were measured and when water levels reached prepumping background conditions, the test was terminated and the packer assembly was removed. Water level data recorded during the straddle-packer tests are shown in **Appendix C**.

Aquifer Performance Tests (APTs)

Two APTs were conducted on the FAS at this site. During the first APT, Well PBF-6 served as the pumped well during the APT and Well PBF-3 served as the observation well. During the second APT, Well PBF-6 also served as the pumped well and PBF-4 served as the observation well. The APTs were conducted by installing a 10-inch diameter submersible pump into Well PBF-6. The test pump was lowered approximately 100 feet into the well on 10-inch diameter steel discharge pipe. Three-phase electricity was applied to the pump by an on-site generator. Flow rates were measured using a 10-inch diameter orifice weir with an 8-inch diameter orifice plate and verified by an in-line flowmeter.

The first APT was conducted to test the upper FAS producing zone from 1,050 feet bls and the open hole extended to 1,252 feet bls. That pumping test was conducted at a pumping rate of 1,630 gpm with a pumping duration of 72 hours.

The second APT was conducted to test the middle FAS producing zone from 1,360 feet bls to 1,510 feet bls. That pumping test was conducted at a rate of 1,320 gpm for a duration of 90 hours.

Background water levels were recorded for approximately one day prior to the start of each APT. During the tests, water levels were measured with an In-Situ Inc. pressure transducers (30 and 50 psi) connected to a Hermit Series 2000 data logger. All APT details are provided in **Appendix D**. A barometer also was used to measure

atmospheric pressure variations during the APTs to determine if a barometric correction to the data was warranted.

Water samples were collected after several hours of continuous pumping during each of the APTs to provide composite water quality data on the pumped interval. The samples were analyzed for standard field parameters with a Hydrolab water quality meter, then transported to the District's laboratory for further analysis.

SITE GEOLOGY

Strata encountered during the construction of Wells PBF-3-4-5 and PBF-6 range in age from middle Eocene (oldest) to Holocene (most recent). These stratigraphic units (in descending order) were as follows: undifferentiated Holocene, Pleistocene, and Pliocene age sediments; the Hawthorn Group of Miocene and late Oligocene age; the Suwannee Limestone of early Oligocene age, and the Ocala Group and Avon Park Formation of Eocene age. **Figure 6** presents a hydrostratigraphic summary of the site, including depths, lithologic column, geologic age, formation names, and hydrogeologic units. The stratigraphic interpretation was derived primarily from the formation samples of Well PBF-3, and described by the FGS provided in **Appendix A**.

Undifferentiated Holocene, Pleistocene, and Pliocene Series

From land surface to a depth of approximately 305 feet bls, the lithology consisted primarily of sand, shells, and limestone of the undifferentiated Holocene, Pleistocene, and Pliocene series. The uppermost 70 feet was primarily unconsolidated, medium- to coarse-grained quartz sand. From 70 to 305 feet bls, the lithology was primarily competent limestone (packstone to grainstone) with quartz sand. These deposits were identified as equivalents of the Pamlico Sand, the Anastasia Formation, and the Tamiami Formation. The top of the Hawthorn Group was identified at 305 feet bls.

Hawthorn Group

The Hawthorn Group was identified between the depths of 305 and 890 feet bls at the site. The upper boundary of the late Oligocene and Miocene-age Hawthorn Group is commonly characterized by a variable siliclastic and phosphate content, a gray to olive green color, and a relatively high gamma-ray log response. The Hawthorn Group as defined by Scott (1988) is divided into the Peace River Formation, which overlies the Arcadia Formation. Although these two formations were not distinguished during this project, the Hawthorn Group at the site was generally represented by an upper interval comprised of olive colored silty clay (between 305 feet and 800 feet bls) and a lower interval comprised of thinly bedded limestone, sand, and silt (between 800 and 890 feet bls).

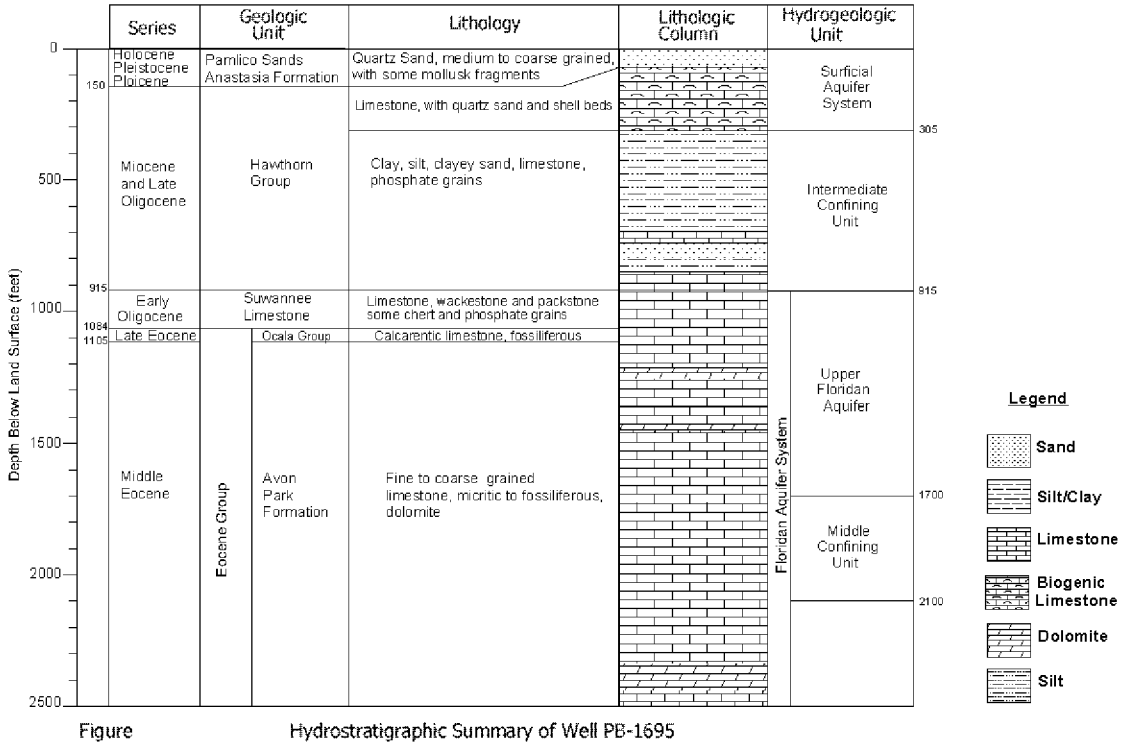

Figure Hydrostratigraphic Summary of Well PB-1695

Figure 6. Hydrostratigraphic Summary Diagram.

Suwannee Limestone

The Suwannee Limestone of early Oligocene age was identified from 890 to 1,084 feet bls based on lithologic descriptions by the District's site geologist and the FGS. The Suwannee Limestone at this site is generally described as yellowish-gray limestone (packstone to wackestone) with calcilutite matrix, with some fossils, chert, and phosphatic grains. This interval was included as part of the "Basal Hawthorn Unit" in Reese and Memberg, 2000.

Eocene Group

The boundary between the Suwannee Limestone and the Eocene Group at the site was determined at a depth of 1,084 feet bls, based on the FGS lithologic interpretation. Identification of distinct Eocene-aged geologic formations in South Florida is difficult due to similarities in lithology and geophysical log responses. Difficulties in differentiating individual formations within the Eocene section from well cuttings has long been recognized by workers in the area, and was most recently discussed by Powers and McNeal (2000). Therefore, these formations have been grouped together and are informally referred to as the "Eocene Group" in this report. Descriptions of the two uppermost (most recent) geologic units within the Eocene Group and their occurrence at the site are summarized below.

Ocala Limestone

Between the depths of 1,084 and 1,105 feet bls, a poorly indurated, yellowish gray, fossiliferous, calcarenitic limestone was described by the FGS from drill cuttings. This "transitional Ocala" interval probably represents reworked sediments as part of a regional unconformity that exists at the top of the Eocene section of South Florida. The first occurrence of a clean, competent limestone at the site was found at a depth of 1,060 feet bls. Generally, the lithology of the Ocala Limestone varies from micritic or chalky limestone, to a medium-grained calcarenitic or coquinoid limestone. It is characterized by abundant larger benthic foraminifera, such as *Operculinoids sp.*, *Camerina sp.*, and *Lepidocyclina sp.* (Peacock, 1983). *Lepidocyclina sp.* were observed in the cuttings by the FGS in the interval from 1,084 to 1,105 feet bls.

Avon Park Formation

The Avon Park Formation was identified at the site from 1,105 to the bottom of the pilot hole at 2,485 feet bls. The formation consists of fine- to coarse-grained, fossiliferous limestone, with interspersed layers of dolomite. It also occasionally contains a large percentage of fine to medium-grained, moderately to well-sorted carbonate sand. Characteristic foraminifera include *Dictyoconus cookei* and *Dictyoconous americanus*. The first occurrence of these indicator fossils at Well PBF-3 were at a depth of 1,105 feet bls.

FORMATION TESTING RESULTS

The formation testing program at the site included lithologic examination, measurements while drilling (e.g., rate of penetration, weight on bit, drilling characteristics, wellhead water flow), geophysical surveys, straddle packer pumping tests, APTs, water quality analyses, and subsequent measurements of water levels. Raw data and laboratory analyses are contained in the appendices of this report; a summary of the results is provided in this section.

Water Quality Profile with Drilled Depth

Water-quality samples were collected at the wellhead of Well PBF-3 at 30-foot intervals while reverse-air drilling through the FAS. The recorded data consisted of chloride concentration, specific conductivity, temperature and pH. The water quality data is presented on **Table 3**. A graph of chloride and conductivity concentrations as a function of depth is presented on **Figure 7**. Chloride concentration increased from 2,985 mg/L to 4,995 mg/L, then the between 1,766 to 1,799 bls the concentration increased again from 4,995 mg/L to 5,725 mg/L. Water quality data was not available in the interval between 1,600 feet bls and 1,900 feet bls; however, at the depth of 1,900 feet bls, the water exhibited a chloride concentration of approximately 4,000 mg/L. Using a relationship developed in Reese (1994), a chloride concentraton of 4,000 mg/L would correspond to a total dissolved solids concentration of approximately 10,000 mg/L. This data was used in combination with geophysical log interpretation to establish that the base of the USDW was present at a depth of 1,766 feet bls at the site.

Water between 1,766 and 2,050 feet bls exhibited chloride concentrations between 3,810 mg/L and 4,500 mg/L, which represented an interval of relatively poor quality water. Between the depths of 2,050 and 2,400 feet bls, the water became somewhat fresher, exhibiting chloride concentrations of approximately 2,500 mg/L. At a depth of 2,400 feet bls, a sharp transition in water quality is observed. Below 2,400 feet bls, the salinity of the water was near that of the concentration of seawater, exhibiting a chloride concentration of approximately 20,000 mg/L.

Geophysical Logs

Geophysical logs were conducted in Well PBF-3-4-5 and Well PBF-6 by the drilling contractor (using Century Geophysical logging equipment) to complement lithologic samples, identify formation boundaries, correlate between wells, and obtain specific information pertaining to the geologic formations and aquifers including delineation of producing zones. Geophysical log traces for several of the logging runs were digitized and are provided in **Appendix B**. Original geophysical log and video surveys are archived and available for review at the District headquarters in West Palm Beach.

*- average

Gamma-Ray Log

The gamma-ray log exhibits low counts (less than 50 API units) throughout the interval between 915 and 1,106 feet bls. This response is indicative of a relatively "clean" limestone, containing little clay or phosphate. Between 1,106 to 1,730 feet bls, counts are relatively higher (40 to 100 API) indicative of a dolomitic limestone interval. Below this dolomitic interval, from 1,730 to 2,489 feet bls, the gamma-ray counts indicate relatively clean limestone (less than 25 API) with the exception of a thin (dolomitic) interval between 2,150 to 2,250 and between 2,440 to 2,447 feet bls where they exceed 60 API.

Caliper Log

From the top of the FAS, to about 1,800 feet bls the caliper log of Well PBF-3-4-5 reflected a high level of definition and variability and ranged between 10 - 18 inches in diameter. The high definition indicated significant variability and bedding planes in the section. Below this depth, the borehole exhibited a smooth wall surface, consistent with softer limestone layers.

Formation Resistivity Logs

Within the FAS, the formation resistivity log tracked between approximately 10-20 ohm-meters through most of the open-hole section between 970 feet to 1,640 feet bls. This may be partially due to the washed out borehole. The Suwannee Limestone interval between 940 to 970 feet bls, displayed higher resistivity values between 25 to 75 ohm-meters, indicative of hard limestone. Field notes indicated bit penetration slowed considerably across this zone while drilling. Additional thin resistive (25 to 50 ohm-meters) beds are seen between the following intervals (in feet bls): 1,296 to 1,320; 1,390 to 1,395; 1,446 to 1,465; 1,565 to 1,578; 1,616 to 1,640; and 1,700 to 1,790. These thin beds are hard, dense, thinly-bedded limestone and dolomites. Below 1,790 feet bls, resistivity falls below 2 ohm-meters which corresponds with the degrading (higher salinity) water quality observed below the USDW (at 1,800 feet bls) while drilling.

Flowmeter and Fluid Resistivity Logs

The producing zones within the FAS are commonly characterized by secondary porosity features such as solution cavities and fracturing. Discrete flow zones exist within the vertical section of FAS wells which, cumulatively, contribute to the total flow observed at the wellhead. Logs particularly useful in delineating flow zones while the well is flowing include the down-hole video survey, flowmeter, fluid resistivity and temperature logs. Review of these logs indicated that flow zones in well PBF-3-4-5 occurred within the following intervals:

- 1,050 to 1,190 feet bls
- 1,220 to 1,304 feet bls
- 1,360 to 1,500 feet bls

Temperature Log

The temperature profile indicates a gradual decrease (cooling) from 72° F at 1,055 feet bls to 67.3 °F at 2,489 feet bls. Subtle deviations from this gradual trend appear to coincide with flow zones.

Most of the flow zones were observed in the upper portion of the Eocene Group between 1,050 feet and 1,500 feet bls. A visual display of the depths at which the flow zones occurred, as well as an overall hydrogeologic interpretation summary of the site is presented in **Figure 8**.

Straddle-Packer Pumping Test Results

Straddle-packer pumping tests were conducted during drilling operations to isolate four selected FAS zones in Well PBF-3 as shown in **Figure 8**. Summaries of the packer test logistics and analyses are provided in **Tables 4** and **5**. Packer test field summary sheets and time drawdown plots are provided in **Appendix C**.

Table 4. Straddle Packer Pumping Test Logistics Summary.

Packer Test Number	Interval (ft. bls)	Date	Static Water Level (ft. NGVD)	Pumping Rate (gpm)	Total Pumping Time (min)
1	1,246 – 1,304	1/4/96	46.6	100	66
2	2,340 – 2,485	2/2/96	13.8	60	265
3	1,360 – 1,500	2/9/96	42.8	108	130
4	1,050 – 1,190	2/12/96	40.53	107	108

Static water level is reported uncorrected for equivalent freshwater head.
Land surface surveyed to 21.53 feet above NGVD 1929.

Table 5. Straddle Packer Test Hydraulic Summary.

Packer Test Number	Interval (ft. bls)	Test Interval Thickness (feet)	Pumping Rate (gpm)	Drawdown (feet)	Transmissivity (ft^2/day)	Hydraulic Conductivity (feet/day)
1	1,246 – 1,304	58	100	22	8,360	144
2	2,340 – 2,485	145	60	75	990	7
3	1,360 – 1,500	140	108	14	58,000	414
4	1,050 – 1,190	140	107	13	72,000	514

"ft. bls" denotes "feet below land surface"
"ft*/day" denotes "feet squared per day"
Transmissivity computed by the Theis recovery "straight-line" method

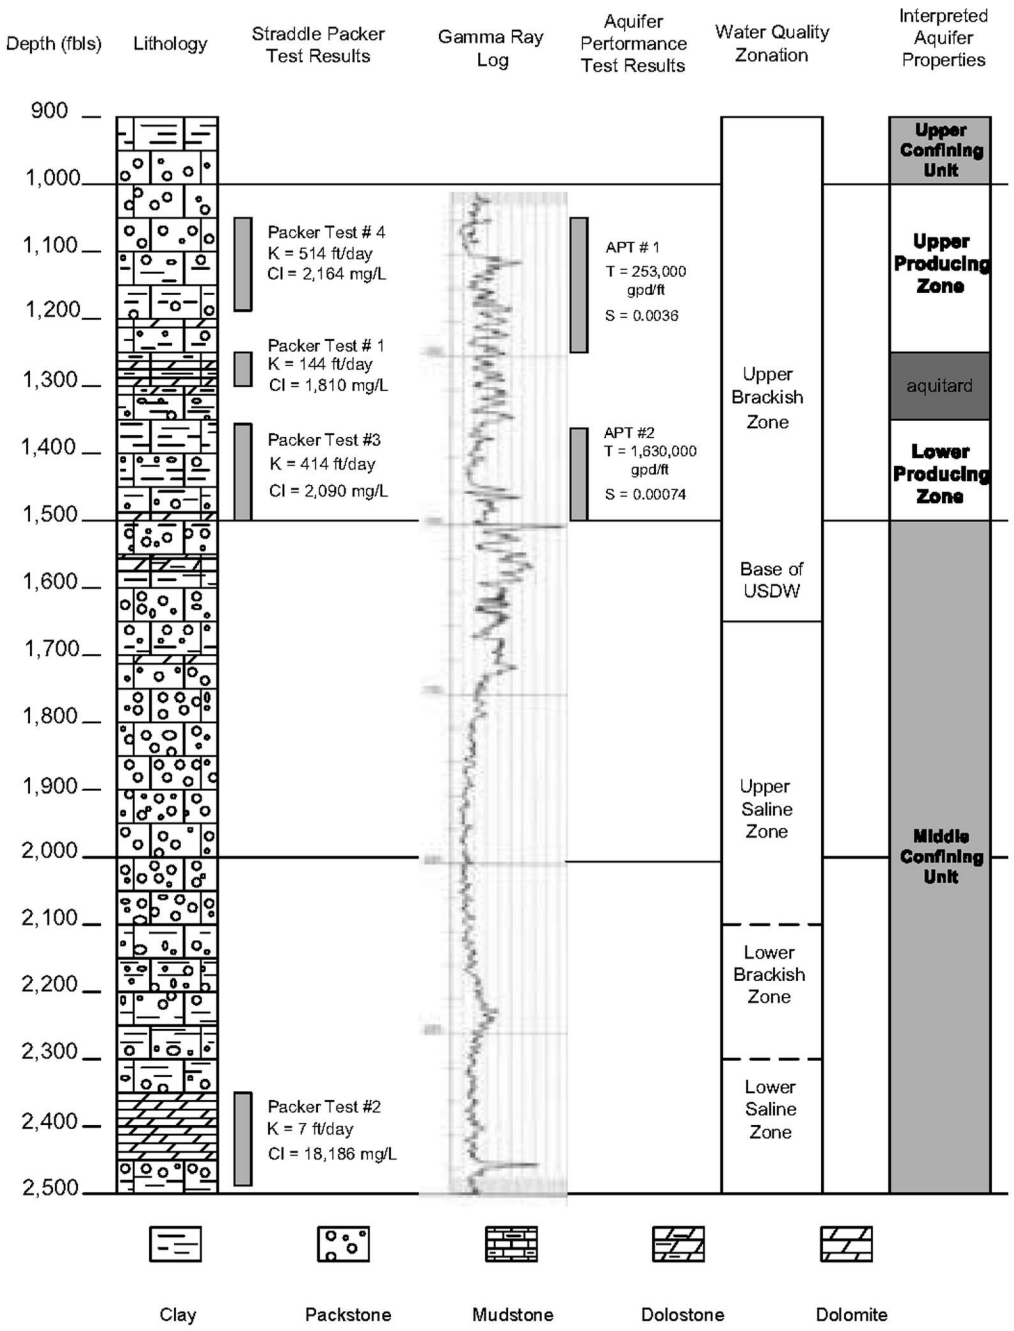

Figure 8. Hydrogeological Intrepretation and Aquifer Characteristics.

Straddle Packer Test No.1

This test was conducted on January 4, 1996, and consisted of pumping an interval between 1,246 and 1,304 feet bls (upper portion of FAS) in Well PBF-3. This interval was pumped for 1 hour at an average discharge rate of 100 gpm. The static water level prior to pumping the well was measured as 46.6 feet above NGVD at the site. The land surface at the site was surveyed at an elevation of approximately 21 feet above NGVD. The maximum measured drawdown while pumping was approximately 22 feet. The specific capacity was calculated as 5 gallons per minute per foot of drawdown (gpm/ft). A transmissivity of 8,360 ft^2/day was estimated using the "straight-line" Theis recovery method. Chloride and TDS concentrations in a water sample collected from the zone were 1,810 mg/L and 3,430 mg/L, respectively.

Straddle-Packer Test No.2

Packer Test No. 2 was conducted on February 2, 1996 and isolated an interval between 2,340 and 2,485 feet bls in PBF-3. The test was conducted by pumping this interval for 4.5 hours at an average rate of 60 gpm. The static water level was measured at 13.8 feet above NGVD. The water level was below land surface at the site. Maximum drawdown measured while pumping was 75 feet and the specific capacity calculated as less than 1 gpm/ft. A transmissivity of 990 ft^2/day was estimated using the "straight line" Theis recovery method. Chloride and TDS concentrations in water sampled from the zone were 18,185 mg/L and 30,900 mg/L, respectively.

Straddle-Packer Test No. 3

Packer Test No. 3 was conducted on February 9, 1996 and isolated the interval between 1,360 and 1,500 feet bls in PBF-3. The test was conducted by pumping this interval for 2 hours at a rate of 108 gpm. The static water level was measured at 42.8 feet above NGVD. The maximum drawdown was 14 feet and the specific capacity calculated as 8 gpm/ft. A transmissivity of 58,000 ft^2/day was using the Theis "straight-line" recovery method. Chlorides and TDS concentrations in water sampled from the zone were 2,090 mg/L and 4,150 mg/L, respectively.

Straddle-Packer Test No. 4

Packer Test No. 4 conducted on February 12, 1996 and isolated an interval between 1,050 and 1,190 feet bls in PBF-3. The test was conducted by pumping this interval for 2 hours at an average rate of 107 gpm. The static water level was measured as 40.53 feet above NGVD. The maximum measured drawdown was 13 feet and the specific capacity calculated as 8.2 gpm/ft. A transmissivity of 72,000 ft^2/day was using the Theis "straight line" recovery method. Chlorides and TDS concentrations in water sampled from the zone were 2,160 mg/L and 4,210 mg/L, respectively.

Aquifer Performance Tests (APTs)

Two APTs were conducted to evaluate subsurface hydraulics and water quality characteristics of the FAS. The results of these tests, including interval tested, static water level, maximum drawdown, pumping rate (Q), transmissivity, storage coefficient, and analytical methods are listed in **Table 6**. In addition, detailed APT summary sheets and time-drawdown plots are provided in **Appendix D**.

Table 6. Aquifer Performance Test Analysis Summary.

Well Name	Interval (ft. bls)	Static Water Level (NGVD 1929)	Maximum Drawdown (ft.)	Pumping Rate (gpm)	Transmissivity (ft^2/day)	Storage Coefficient	r/B	Method of Analysis
APT No. 1								
PBF - 6	1,050 – 1,250	53.2	12.2	1,640	33,800	nc	nc	Jacob
PBF - 3	1,050 – 1,250	-	2.2	-	40,300	2.6×10^{-3}	nc	Cooper-Jacob
PBF - 3	1,050 – 1,250	-	2.2	-	34,300	3.6×10^{-3}	0.2478	Hantush
APT No. 2								
PBF-6	1,360 – 1,510	-	-	1,320	196,000	nc	nc	Theis Recovery
PBF-4	1,360 – 1,510	44.3	1.1	-	231,300	6.5×10^{-4}	nc	Cooper-Jacob
PBF - 4	1,360 – 1,510	44.3	1.1	-	198,500	8.5×10^{-4}	0.1	Hantush

APT No.1

On April 30, 1996, APT No. 1 was conducted over the open-hole interval from 1,050 to 1,250 feet bls. This APT consisted of pumping Well PBF-6 for 60 hours at a constant discharge rate of 1,640 gpm, while monitoring water levels in PBF-3. The static water level in Well PBF-6 was measured as 53.2 feet above NGVD prior to the initiation of pumping. The specific capacity in the pumped well was estimated at 40 gpm/ft. The maximum drawdown during pumping recorded at the observation well (located 260 feet away) was 2.2 feet. A transmissivity of 34,300 ft^2/day and storage coefficient of 3.6×10^{-3} were estimated based on a log-log plot of the time-drawdown data (**Appendix D**) using the Hantush (1956) leaky analytical solution method. Since the tested interval had a thickness of 200 feet, a hydraulic conductivity of 1,720 feet per day was estimated. An r/B of 0.2478 was estimated using the Hantush (1956) method.

APT No.2

The second APT was conducted on July 1, 1996, and consisted of pumping the interval between 1,360 to 1,510 feet bls (middle portion of upper FAS) in Well PBF-6 for 69 hours at a constant discharge rate of 1,320 gpm, while monitoring water levels in Well

PBF-4. The static water level in Well PBF-6 was measured as 44.3 above NGVD prior to the initiation of pumping. The maximum drawdown measured in the observation well during pumping was 1.1 feet. A transmissivity of 198,500 ft^2/day and storage coefficient of 8.5 X 10^{-4} were estimated based on a semi-log plot of the time-drawdown data (**Appendix D**) using the Hantush (1956) method. Since the tested interval had a thickness of 150 feet, the hydraulic conductivity was estimated at 1,320 feet per day. A leakance of 0.257 gallons per day per cubic foot and an r/B of 0.1 was estimated using the Hantush (1956) method.

Water Quality from the Pumping Tests

Chlorides and TDS concentrations in water sampled from the zone between 1,050 and 1,252 feet bls during APT No. 1 were 2,160 mg/L and 4,050 mg/L, respectively. Chlorides and TDS concentrations in water sampled from the zone between 1,360 and 1,510 feet bls during APT No. 2 were 2,159 mg/L and 3,960 mg/L, respectively. **Table 7** lists the analytical results of water quality samples collected during the APTs and **Table 8** describes the results of water quality analyses from straddle-packer pumping tests. The data indicates that water in the upper and middle zones are very similar, however, water in the uppermost FAS is slightly more saline than water in the middle portion of the upper FAS.

Table 7. Summary of Water Quality Data from Aquifer Performance Tests.

APT Test Number	Well Name	Sample Depth	Na mg/L	K mg/L	Ca mg/L	Mg^{2+} mg/L	Cl mg/L	SO_4 mg/L	Alk. As $CaCO_3$ mg/L	F mg/L	TDS mg/L	pH s.u.	SC mmhos/cm

The chemical composition of groundwater within the FAS is influenced by several factors including lithology, flow patterns, presence of solution features, and residence time. The hydrochemical facies of groundwater can be classified on the basis of the dominant ions by means of a trilinear diagram and an ionic strength analysis described by Frazee (1982). **Table 9** presents the computation of the relative strengths of the major

cations and anions in the water samples collected during the straddle-packer tests. The analyses from Straddle Packer Tests Nos. 1, 3, and 4 indicated good agreement between the computed relative strength of positive and negatively charged ions. The analysis of the relative ionic balance from Packer Test No. 2 did not show good agreement, indicating that the accuracy of the laboratory results may be in question. This may be due to the high salinity of the water from this zone. Major ions from water samples obtained from Well PBF-6 during the APT's were plotted in the trilinear diagram shown in **Figure 9**. The points plotted in very similar positions on the diagram defined as "lateral intrusion or seawater origin" facies as defined in Frazee (1982), which is dominated primarily by the sodium and chloride ions.

Depth of the Base of the Underground Source of Drinking Water (USDW)

The base of the Underground Source of Drinking Water (USDW) is defined by the state of Florida as the depth to which water containing a TDS concentration of less than 10,000 mg/L extends. The concentration of TDS in water sampled between 2,340 feet and 2,485 feet bls during Packer Test No. 2 was 30,900 mg/L, placing it below the base of the USDW. The concentration of TDS sampled between 1,050 feet and 1,510 feet bls during Packer Test Nos. 1, 3, and 4 was between 3,430 and 4,210 mg/L, which is above the base of the USDW. The water quality results from these packer tests were used in combination with the geophysical log analysis and water sampled during reverse air drilling (**Table 3**) to determine that the base of the USDW was at a depth of approximately 1,766 feet bls at the site.

Water Levels

Water levels in PBF-3-4-5 were measured monthly during the period from April 1997 to March 2001 and used to develop the hydrograph shown in **Figure 10**. Water levels are referenced to NGVD of 1929. The hydrograph (**Figure 10**) shows how water levels (unadjusted for density) in the upper FAS are approximately 36 feet higher than in the lower FAS. Water from the lower FAS (PBF-5) is more saline and thus heavier than water in the upper FAS. The mean water level for the period of record (April 1997 to March 2001) for the upper and lower FAS zones at the site were approximately +46 feet and +10 feet NGVD, respectively. Since the elevation of land surface at the site is approximately +21 feet NGVD, the upper FAS zones flow naturally at land surface under approximately 25 feet of artesian pressure while the lower FAS zone does not. Water levels fluctuated within a range of approximately 2 feet above and below the average values during the period of record.

Equivalent Freshwater Head Correction

The "raw" water levels recorded at the wellhead were converted to "equivalent freshwater heads" using the Ghyben-Herzberg method (Herzberg, 1901). To perform the correction, the specific gravity of the water collected from each of the monitor zones was computed, the results of which are presented in **Table 10**. Freshwater equivalent heads for the upper, middle, and lower FAS zones are shown in **Table 11**.

Table 10. Specific Gravity Calculation for Water from Well PBF-3, PBF-4, and PBF-5.

Monitor Zone	Total Dissolved Solids (mg/L)	Specific Gravity (g/cm^3)
PBF-3	4,590	1.0025
PBF-4	3,910	1.0025
PBF-5	32,200	1.0225

Table 11. Equivalent Freshwater Heads (September 1997).

Monitor Zone	Depth Interval (feet, bls)	Uncorrected Elevation (feet, NGVD)	Corrected Elevation (feet, NGVD)
PBF-3 (Upper FAS)	1,050 – 1,252	46.78	49.53
PBF-4 (Upper FAS)	1,360 – 1,510	47.13	51.02
PBF-5 (Lower FAS)	2,340 – 2,490	9.27	65.50

Examination of the density-corrected water levels indicates that the lower FAS actually exhibits higher water levels than those in the upper and middle zones. Water levels in the upper and middle zones are nearly identical. This infers that groundwater flow at the site is upward, from the lower FAS towards the upper FAS.

Depth to Top of Seawater

The concentration of TDS in water sampled from between 2,340 feet and 2,485 feet bls during Packer Test No. 2 was 30,900 mg/L, which was equivalent to that of sea water. To approximate the depth to the top of the salt water interface, the Ghyben-Herzberg equation (Herzberg, 1901) was utilized, wherein the depth to salt water can be approximated at 40 times the height of the fresh water above sea level. Since the equivalent freshwater heads in the upper FAS were approximately 47 feet above NGVD as shown on **Table 11**, the computed depth to the top of sea water at the site was estimated at approximately 1,880 feet NGVD.

SUMMARY

Two new wells were constructed in east-central Palm Beach County as part of a program to obtain hydrogeologic and water quality data from the FAS within the District's LEC Planning Area. Hydrogeologic information was obtained to a depth of 2,400 feet bls from the wells. The main findings of the construction and testing program were as follows:

Surficial sediments extended from land surface to a depth of 305 feet bls and the Hawthorn Group (upper confining unit) was found to extend to approximately 915 feet bls. Limestone comprising the uppermost portion of the FAS was identified at a depth of approximately 890 feet (bls) based on lithologic and hydrogeologic observations.

An "upper" producing zone between 1,050 to 1,250 feet bls exhibited a transmissivity of 34,300 ft^2/day. Water sampled from that interval exhibited a chloride concentration of approximately 2,160 mg/L. A "middle" producing zone was identified between 1,360 and 1,510 feet bls. This interval had a transmissivity of approximately 198,500 ft^2/day. Water collected from this zone also had a chloride concentration of 2,160 mg/L.

The base of the USDW was identified by water quality analysis during drilling, straddle-packer tests, and geophysical log analysis. This base was found to occur at approximately 1,766 feet bls at the site. The calculated depth to the top of salt water at the site was approximately 1,880 feet bls, based on the Geyben-Herzberg equation.

A zone between 2,340 and 2,485 feet bls within the FAS exhibited a very low hydraulic conductivity (7 feet/day), indicating significant confinement at that depth. It also had a chloride concentration of 18,185 mg/L, about that of seawater.

The unadjusted potentiometric surfaces of the upper and middle monitored FAS intervals (Wells PBF-3 and PBF-4) during the period from April 1997 to March 2001 were approximately 47 feet above the 1929 NGVD. The potentiometric surface of the lower monitored interval (Well PBF-5) was approximately 9 feet above NGVD during the same period. Water levels fluctuated approximately 2 feet in monitored zones over a period of nearly four years. When adjusted for density, the groundwater gradient between the upper and lower monitored FAS zones was upward. Density corrected heads in the lower FAS were approximately 15 feet higher than those measured in the upper FAS.

POROSITY: LOW PERMEABILITY; POOR INDURATION
CEMENT TYPE(S): CALCILUTITE MATRIX, CLAY MATRIX
ACCESSORY MINERALS: CALCILUTITE-15%, CLAY-20%
LIMESTONE-02%, PHOSPHATIC SAND-10%
FOSSILS: BENTHIC FORAMINIFERA, FOSSIL FRAGMENTS
ALSO CONTAINS 2% MICA.

530 - 550 SILT; YELLOWISH GRAY TO LIGHT OLIVE
POROSITY: LOW PERMEABILITY; POOR INDURATION
CEMENT TYPE(S): CALCILUTITE MATRIX, CLAY MATRIX
ACCESSORY MINERALS: CLAY-25%, PHOSPHATIC SAND-10%
CALCILUTITE-15%, QUARTZ SAND-05%
FOSSILS: MOLLUSKS, FOSSIL FRAGMENTS, BENTHIC FORAMINIFERA

MIXTURE OF SANDSTONE AND CLAY MUD AND CALCILUTITE, AND 2% MICA.

550 - 690 SILT; LIGHT OLIVE TO LIGHT OLIVE GRAY
POROSITY: LOW PERMEABILITY; POOR INDURATION
CEMENT TYPE(S): CALCILUTITE MATRIX, CLAY MATRIX
ACCESSORY MINERALS: CLAY-20%, PHOSPHATIC SAND-05%
CALCILUTITE-05%, QUARTZ SAND-05%
FOSSILS: MOLLUSKS, FOSSIL FRAGMENTS
SMALL PERCENTAGE OF MICA.

690 - 800 NO SAMPLES

800 - 850 SILT; YELLOWISH GRAY TO OLIVE GRAY
POROSITY: LOW PERMEABILITY; MODERATE INDURATION
CEMENT TYPE(S): CALCILUTITE MATRIX, CLAY MATRIX
ACCESSORY MINERALS: QUARTZ SAND-07%, PHOSPHATIC SAND-10%
CLAY-25%
FOSSILS: FOSSIL FRAGMENTS, BENTHIC FORAMINIFERA, SPICULES
CONTAINS SMALL PERCENTAGE OF MICA AND CHERT CHIPS SAND AND MUDSTONE FRAGMENTS SHOWING POSSIBLE REWORKING.

850 - 915 LIMESTONE; YELLOWISH GRAY TO LIGHT OLIVE GRAY
20% POROSITY: INTERGRANULAR, POSSIBLY HIGH PERMEABILITY
GRAIN TYPE: BIOGENIC, SKELETAL
75% ALLOCHEMICAL CONSTITUENTS
POOR INDURATION
CEMENT TYPE(S): CALCILUTITE MATRIX
ACCESSORY MINERALS: QUARTZ SAND-20%, PHOSPHATIC SAND-05%
SPAR-05%
FOSSILS: MOLLUSKS, BENTHIC FORAMINIFERA, SPICULES
FOSSIL FRAGMENTS
SANDY PHSOPHATIC LIMESTONE WITH CHERT FRAGMENTS FROM A CAVE-IN.

915 - 940 WACKESTONE; VERY LIGHT GRAY TO GREENISH GRAY
15% POROSITY: INTERGRANULAR, POSSIBLY HIGH PERMEABILITY
GRAIN TYPE: BIOGENIC, SKELETAL, CRYSTALS
15% ALLOCHEMICAL CONSTITUENTS
POOR INDURATION
CEMENT TYPE(S): CALCILUTITE MATRIX
FOSSILS: MOLLUSKS, FOSSIL FRAGMENTS
LEPIDOCYCLINA UNDULOSE & SP., CAVE-IN FRAGMENTS OF CHERT MICA, AND SANDY PHOSPHATIC LIMESTONE.

940 - 1040 PACKSTONE; YELLOWISH GRAY TO GREENISH GRAY
20% POROSITY: INTERGRANULAR, POSSIBLY HIGH PERMEABILITY
GRAIN TYPE: BIOGENIC, SKELETAL, PELLET
75% ALLOCHEMICAL CONSTITUENTS
MODERATE INDURATION

CEMENT TYPE(S): CALCILUTITE MATRIX
FOSSILS: BRYOZOA, MOLLUSKS, FOSSIL FRAGMENTS
LEPIDOCYCLINA UNDULOSE & SP., CAVE-IN FRAGMENTS OF CHERT
MICA, AND SANDY PHOSPHATIC LIMESTONE.

1040 - 1050 PACKSTONE; YELLOWISH GRAY TO LIGHT OLIVE GRAY
20% POROSITY: INTERGRANULAR, POSSIBLY HIGH PERMEABILITY
GRAIN TYPE: PELLET, BIOGENIC, SKELETAL
70% ALLOCHEMICAL CONSTITUENTS
MODERATE INDURATION
CEMENT TYPE(S): SPARRY CALCITE CEMENT, CALCILUTITE MATRIX
OTHER FEATURES: MEDIUM RECRYSTALLIZATION
FOSSILS: MOLLUSKS, FOSSIL FRAGMENTS
LEPIDOCYCLINA UNDULOSE & SP., CAVE-IN FRAGMENTS OF CHERT
MICA, AND SANDY PHOSPHATIC LIMESTONE.

1050 - 1084 PACKSTONE; YELLOWISH GRAY
20% POROSITY: INTERGRANULAR, POSSIBLY HIGH PERMEABILITY
GRAIN TYPE: PELLET, BIOGENIC, SKELETAL
75% ALLOCHEMICAL CONSTITUENTS
MODERATE INDURATION
CEMENT TYPE(S): SPARRY CALCITE CEMENT, CALCILUTITE MATRIX
OTHER FEATURES: MEDIUM RECRYSTALLIZATION
FOSSILS: MOLLUSKS, FOSSIL FRAGMENTS, ECHINOID
LEPIDOCYCLINA SP., CAVE-IN FRAGMENTS OF CHERT, MICA, AND
SANDY PHOSPHATIC LIMESTONE.

1084 - 1105 CALCARENITE; YELLOWISH GRAY
30% POROSITY: INTERGRANULAR, POSSIBLY HIGH PERMEABILITY
GRAIN TYPE: BIOGENIC, SKELETAL, CRYSTALS
85% ALLOCHEMICAL CONSTITUENTS
POOR INDURATION
CEMENT TYPE(S): CALCILUTITE MATRIX

FOSSILS: BENTHIC FORAMINIFERA, FOSSIL FRAGMENTS

1455 - 1460 WACKESTONE; YELLOWISH GRAY
25% POROSITY: INTERGRANULAR, POSSIBLY HIGH PERMEABILITY
VUGULAR
GRAIN TYPE: SKELETAL, BIOGENIC, PELLET
30% ALLOCHEMICAL CONSTITUENTS
GRAIN SIZE: FINE; RANGE: VERY FINE TO GRAVEL
GOOD INDURATION
CEMENT TYPE(S): CALCILUTITE MATRIX

OTHER FEATURES: CALCAREOUS, FOSSILIFEROUS, CHALKY
MEDIUM RECRYSTALLIZATION
FOSSILS: CONES, BENTHIC FORAMINIFERA, FOSSIL FRAGMENTS
SAMPLE ALSO CONSISTS OF ARE GRAINSTONE AND MUDSTONE
DICTYOCONUS AMERICANUS.

1460 - 1470 MUDSTONE; WHITE TO YELLOWISH GRAY
POROSITY: INTERGRANULAR, VUGULAR
GRAIN TYPE: SKELETAL, BIOGENIC, PELLET
10% ALLOCHEMICAL CONSTITUENTS
GRAIN SIZE: FINE; RANGE: VERY FINE TO COARSE
GOOD INDURATION
CEMENT TYPE(S): CALCILUTITE MATRIX
OTHER FEATURES: CALCAREOUS, FOSSILIFEROUS, CHALKY
LOW RECRYSTALLIZATION
FOSSILS: CONES, BENTHIC FORAMINIFERA, FOSSIL MOLDS
FOSSIL FRAGMENTS
DICTYOCONUS AMERICANUS.

1470 - 1485 PACKSTONE; YELLOWISH GRAY
15% POROSITY: INTERGRANULAR, POSSIBLY HIGH PERMEABILITY
GRAIN TYPE: SKELETAL, BIOGENIC, PELLET
85% ALLOCHEMICAL CONSTITUENTS
GRAIN SIZE: FINE; RANGE: VERY FINE TO GRAVEL
GOOD INDURATION
CEMENT TYPE(S): CALCILUTITE MATRIX
OTHER FEATURES: CALCAREOUS, FOSSILIFEROUS, CHALKY
FOSSILS: CONES, BENTHIC FORAMINIFERA, FOSSIL MOLDS
FOSSIL FRAGMENTS
DICTYOCONUS AMERICANUS.

1485 - 1490 MUDSTONE; WHITE TO YELLOWISH GRAY
POROSITY: INTERGRANULAR, VUGULAR
GRAIN TYPE: SKELETAL, BIOGENIC, PELLET
10% ALLOCHEMICAL CONSTITUENTS
GRAIN SIZE: FINE; RANGE: VERY FINE TO COARSE
GOOD INDURATION
CEMENT TYPE(S): CALCILUTITE MATRIX
ACCESSORY MINERALS: QUARTZ SAND-01%, DOLOMITE-01%
OTHER FEATURES: CALCAREOUS, FOSSILIFEROUS, CHALKY
LOW RECRYSTALLIZATION
FOSSILS: CONES, BENTHIC FORAMINIFERA, FOSSIL MOLDS
MOLLUSKS
DICTYOCONUS AMERICANUS, SOME GRAINSTONE FRAGMENTS.

1490 - 1495 DOLOSTONE; VERY LIGHT ORANGE TO MODERATE GRAY
25% POROSITY: INTERCRYSTALLINE, VUGULAR
POSSIBLY HIGH PERMEABILITY; 90-100% ALTERED; SUBHEDRAL
GRAIN SIZE: VERY FINE; RANGE: MICROCRYSTALLINE TO FINE
GOOD INDURATION

CEMENT TYPE(S): DOLOMITE CEMENT
ACCESSORY MINERALS: LIMESTONE-05%
OTHER FEATURES: HIGH RECRYSTALLIZATION
VERY POROUS, LARGE VUGS, REMNANT CALCILUTITE PATCHES.

1495 - 1500 PACKSTONE; YELLOWISH GRAY
15% POROSITY: VUGULAR, POSSIBLY HIGH PERMEABILITY
GRAIN TYPE: BIOGENIC, SKELETAL, PELLET
75% ALLOCHEMICAL CONSTITUENTS
GRAIN SIZE: COARSE; RANGE: FINE TO GRAVEL; GOOD INDURATION
CEMENT TYPE(S): CALCILUTITE MATRIX
ACCESSORY MINERALS: DOLOMITE-02%, SPAR-05%
OTHER FEATURES: CHALKY, FOSSILIFEROUS, CALCAREOUS
FOSSILS: CONES, BENTHIC FORAMINIFERA, FOSSIL FRAGMENTS
FOSSIL MOLDS, MOLLUSKS
DICTYOCONUS AMERICANUS.

1500 - 1505 WACKESTONE; YELLOWISH GRAY TO LIGHT GRAY

APPENDIX B - GEOPHYSICAL LOGS

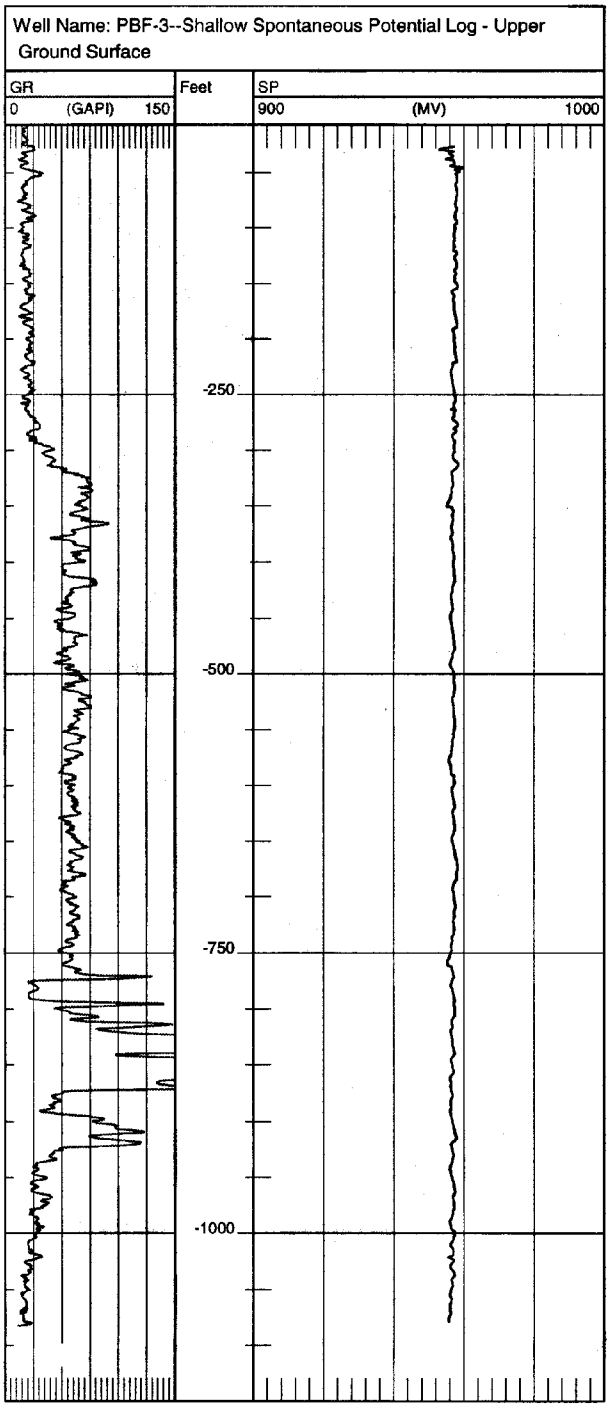

Figure B-1. PBF-3 Shallow Spontaneous Potential Geophysical Log (Ground Surface).

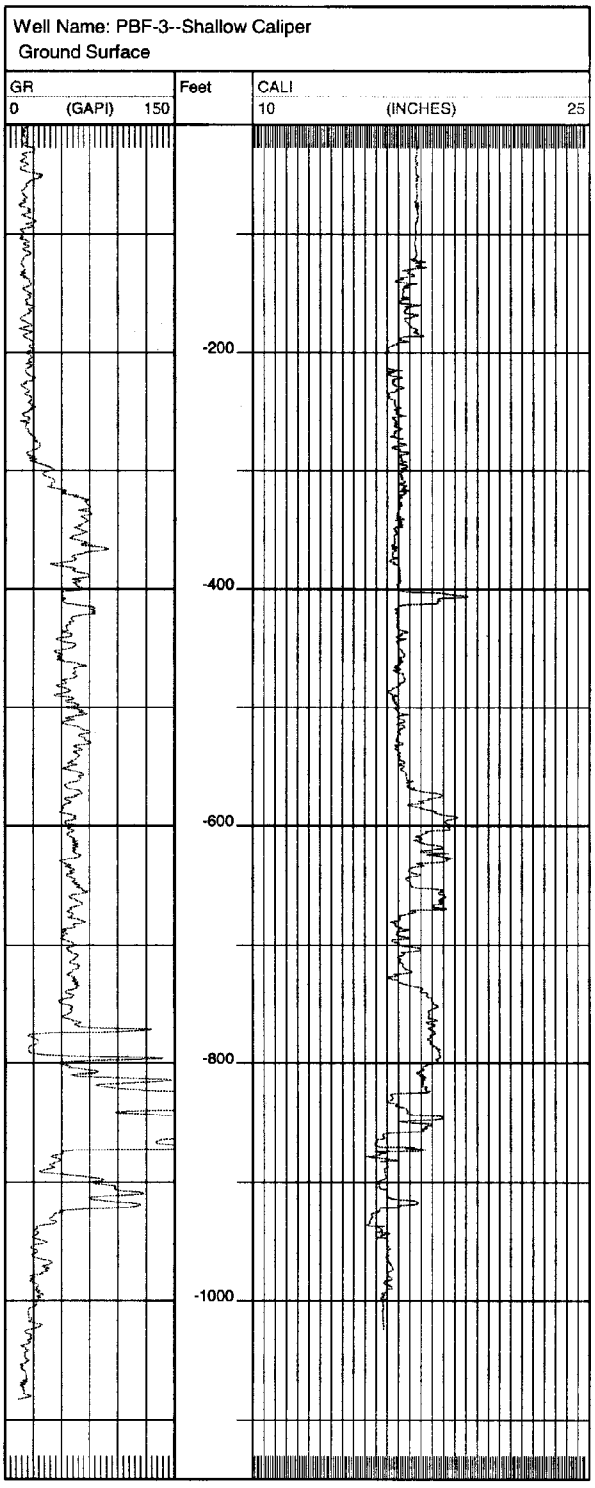

Figure B-2. PBF-3 Shallow Caliper Geophysical Log (Ground Surface).

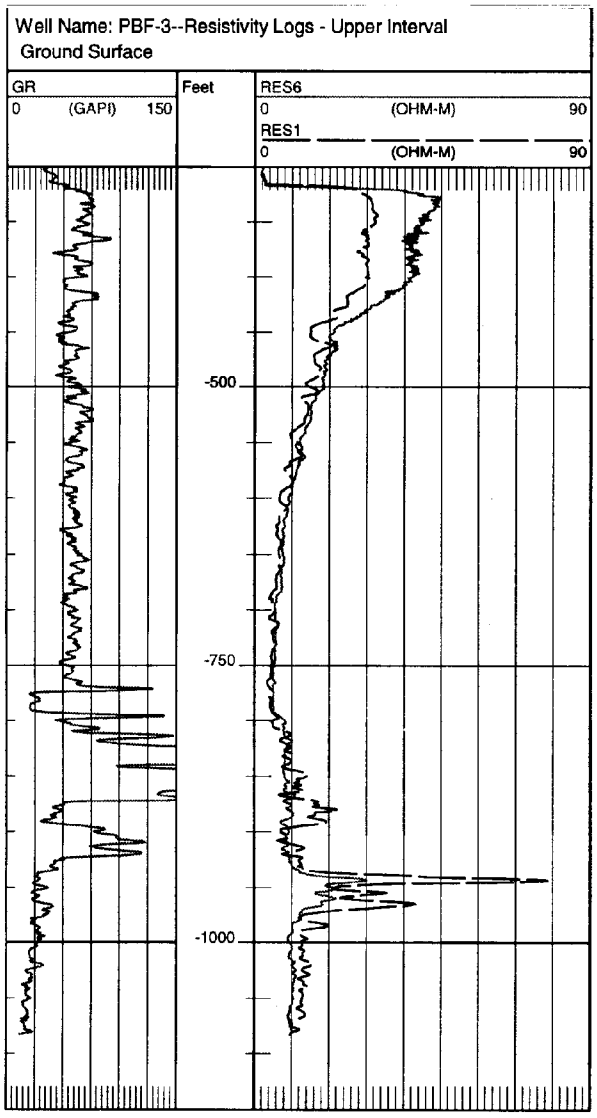

Figure B-3. PBF-3 Resistivity Geophysical Log - Upper Interval (Ground Surface).

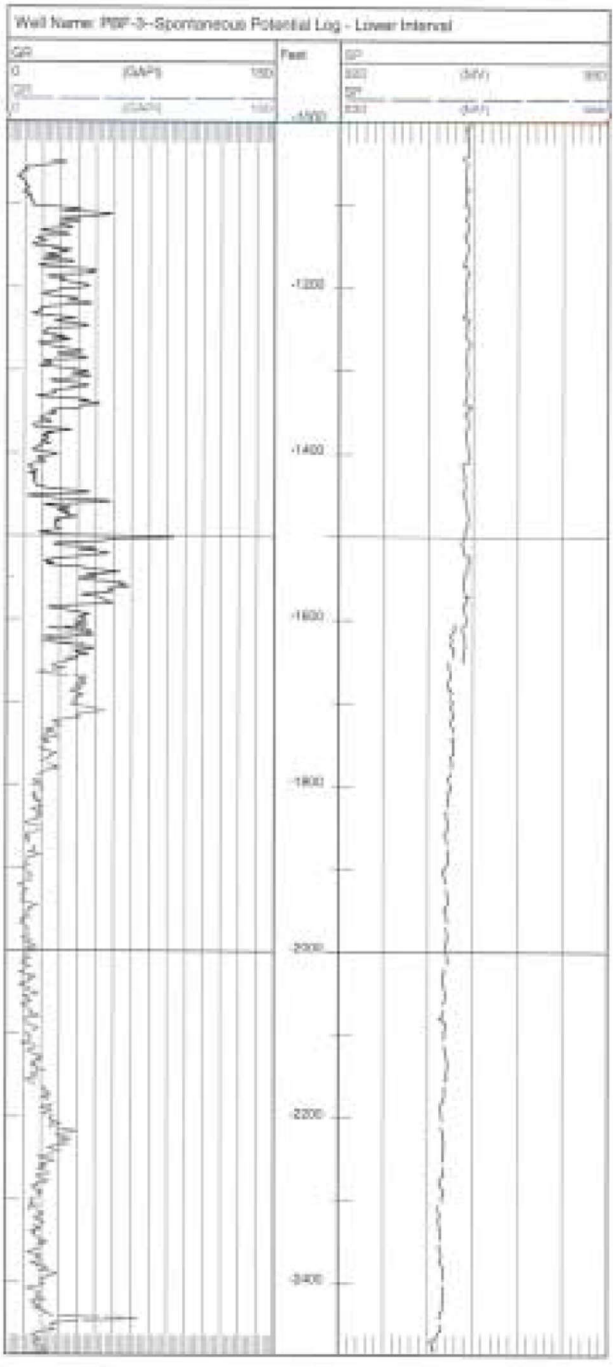

Figure B-4. PBF-3 Spontaneous Potential Geophysical Log (Lower Interval).

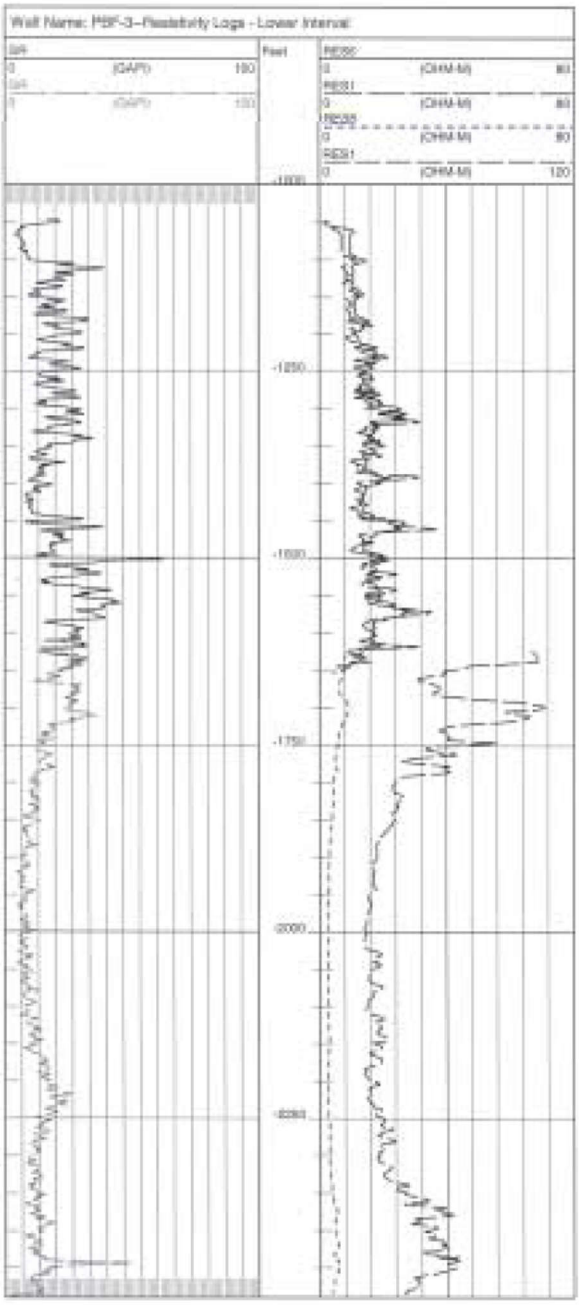

Figure B-5. PBF-3 Resistivity Geophysical Log (Lower Interval).

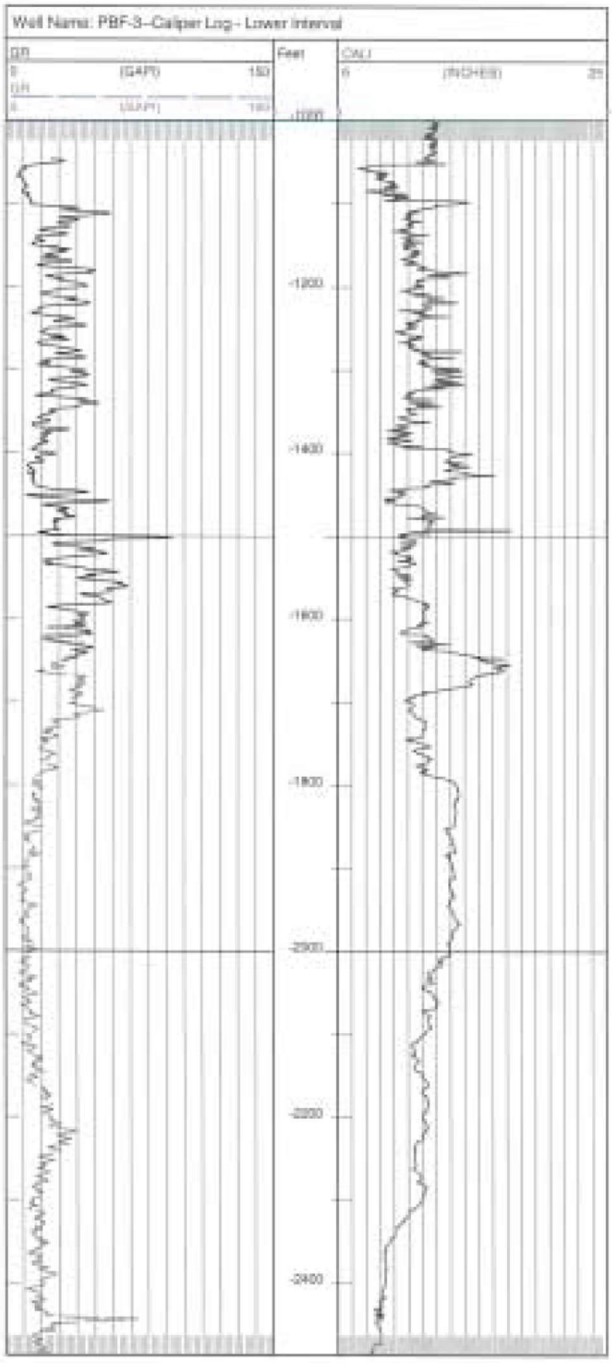

Figure B-6. PBF-3 Caliper Geophysical Log (Lower Interval).

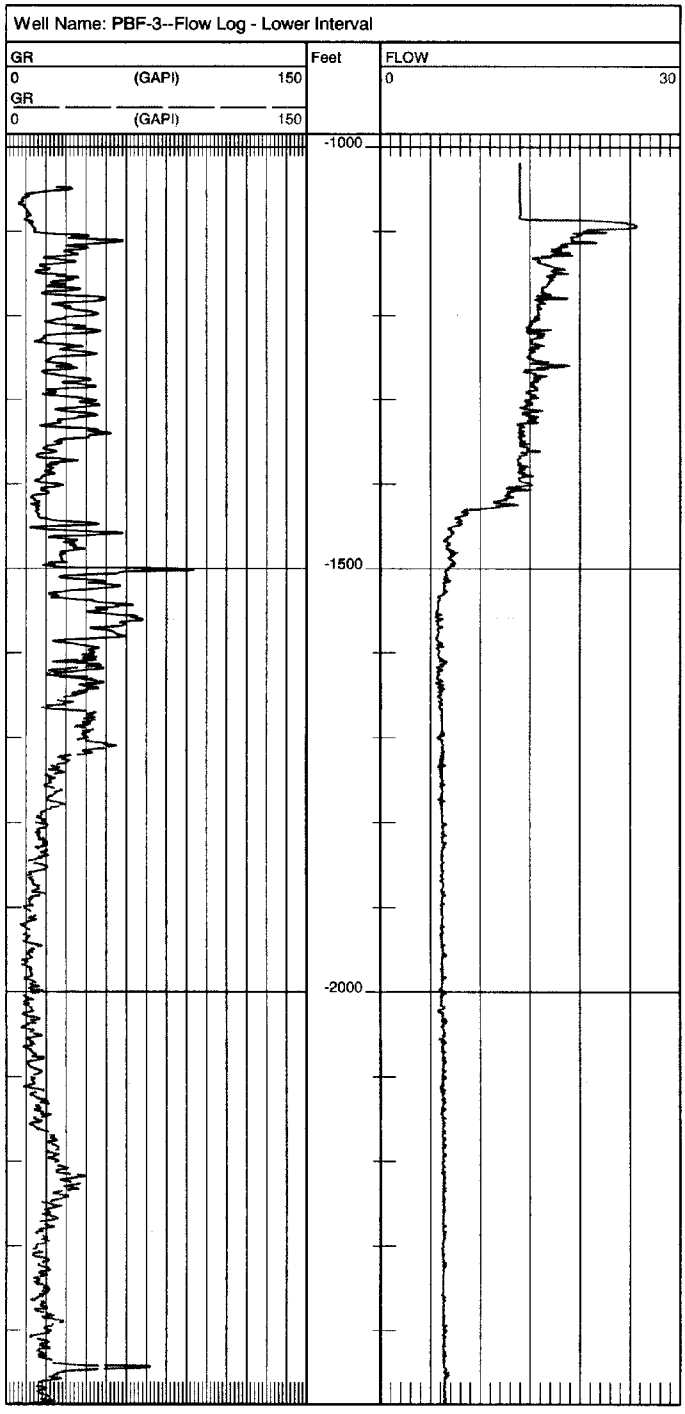

Figure B-7. PBF-3 Flow Log (Lower Interval).

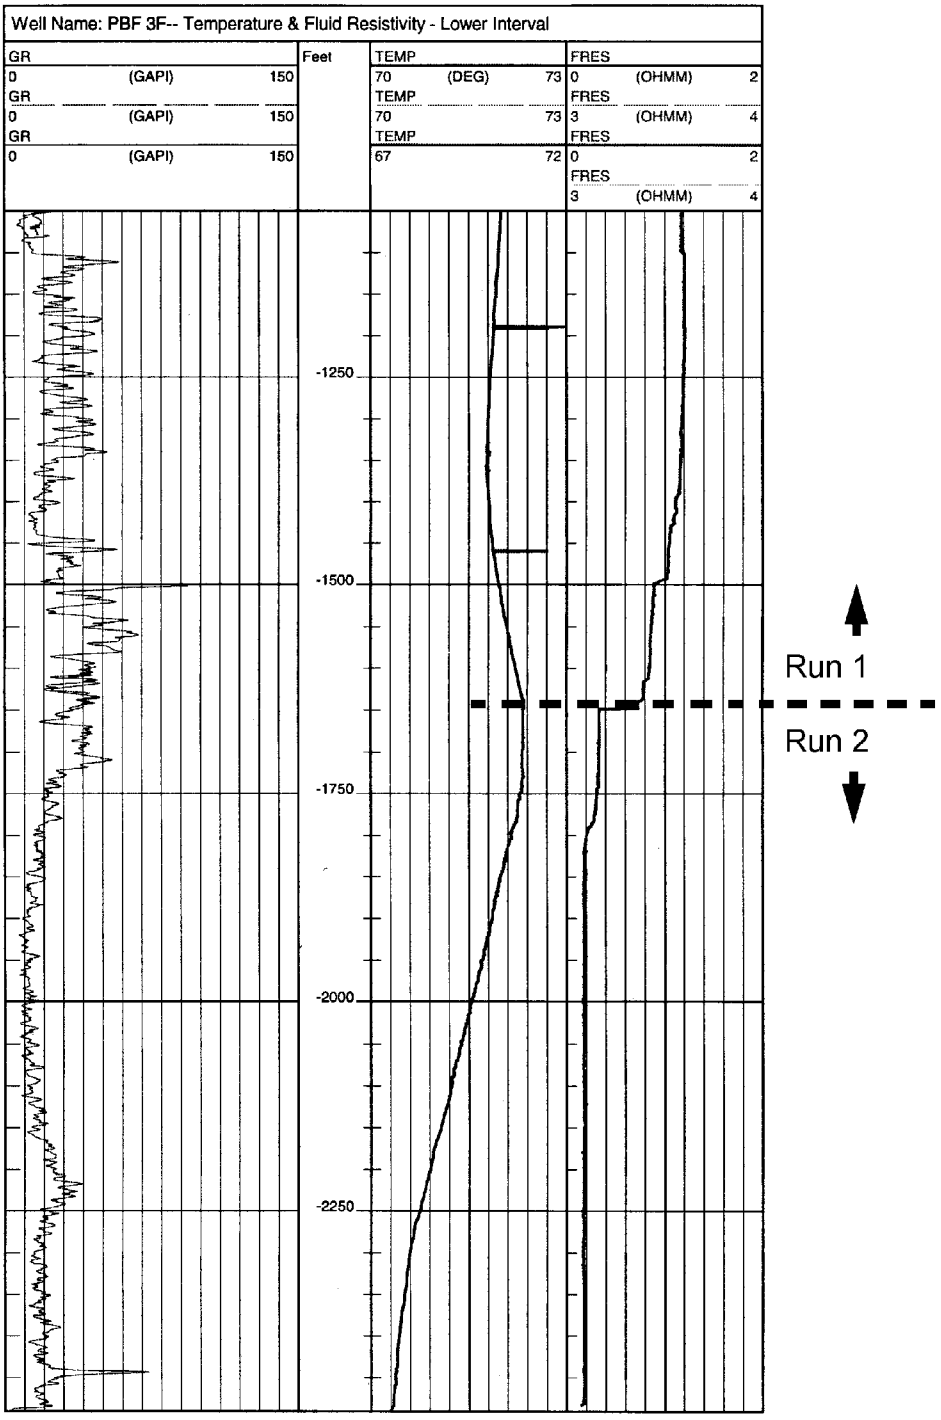

Figure B-8. PBF-3 Temperature and Fluid Resistivity (Lower Interval).

APPENDIX C - PACKER TEST DATA SHEETS AND ANALYSES

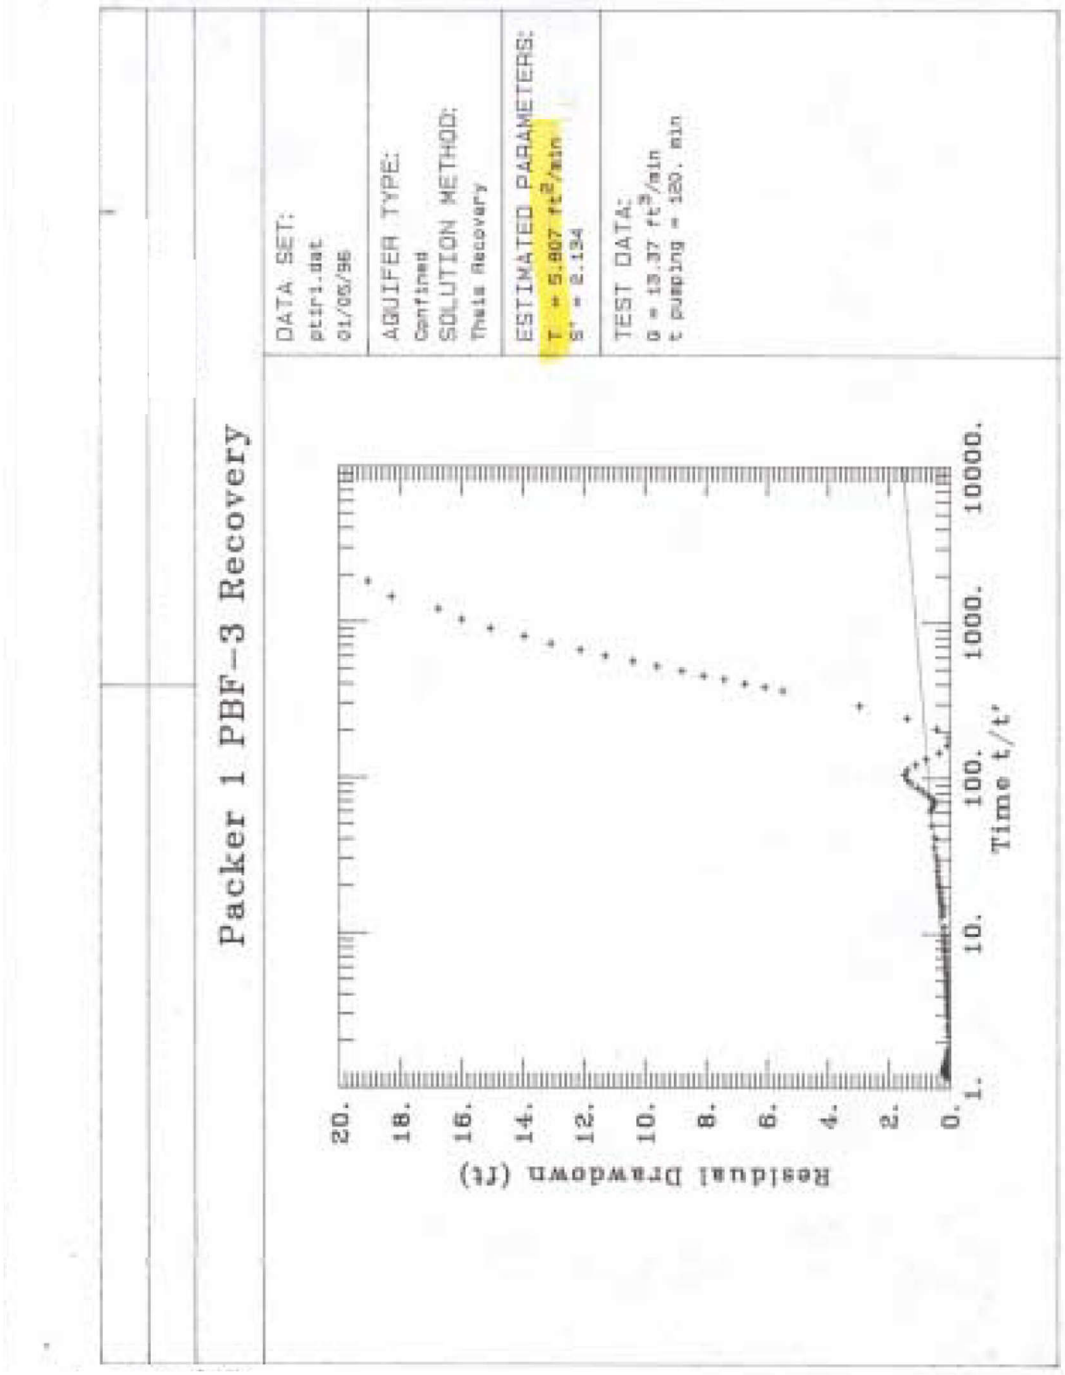

Figure C-1. Recovery Test Data and Analysis (Packer Test 1).

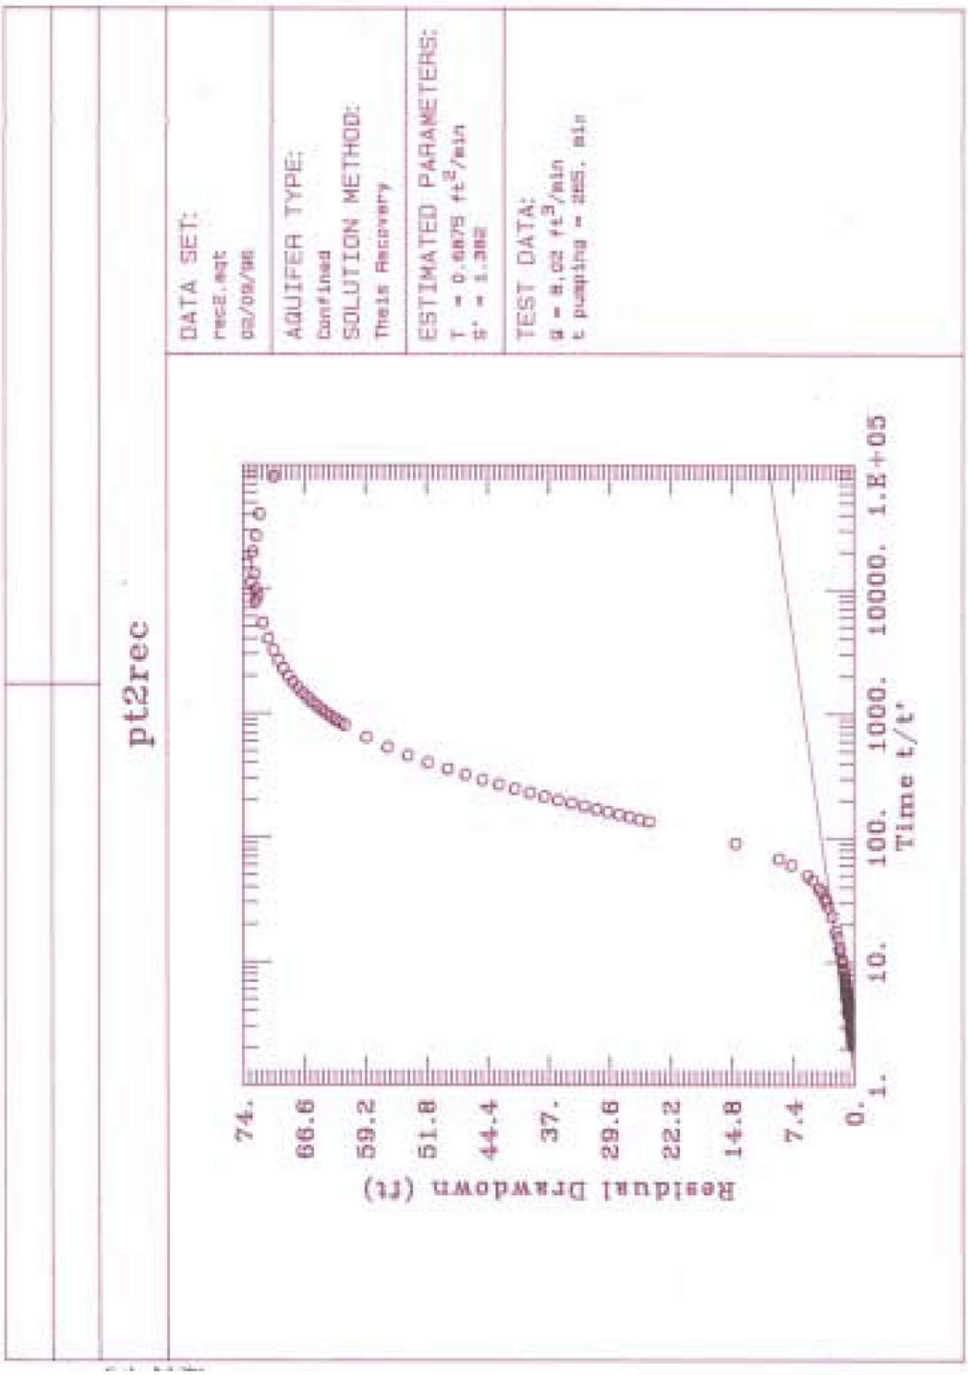

Figure C-2. Recovery Test Data and Analysis (Packer Test 2).

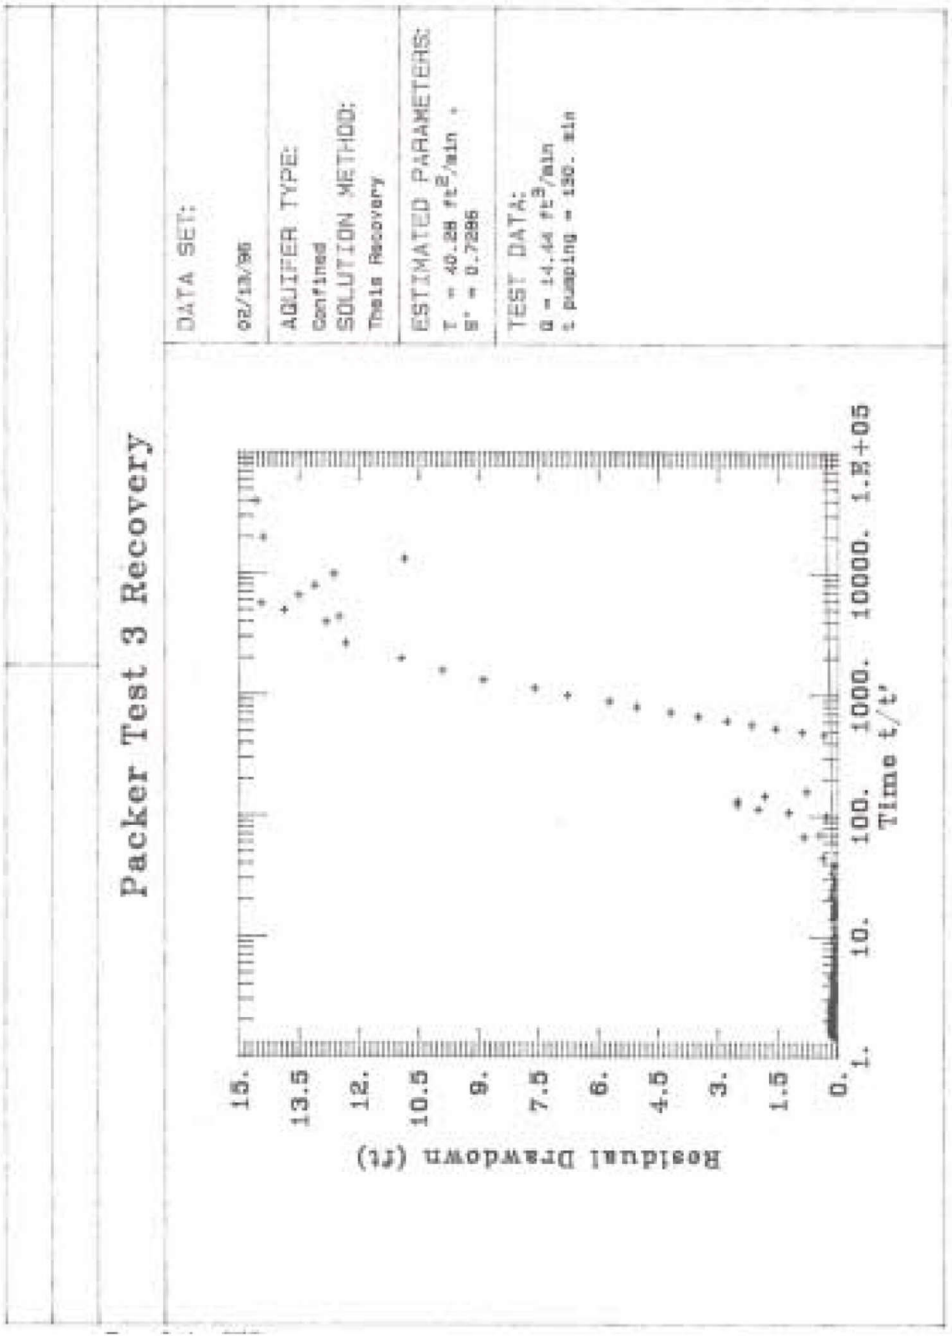

Figure C-3. Packer Test Recovery Data (Packer Test 3).

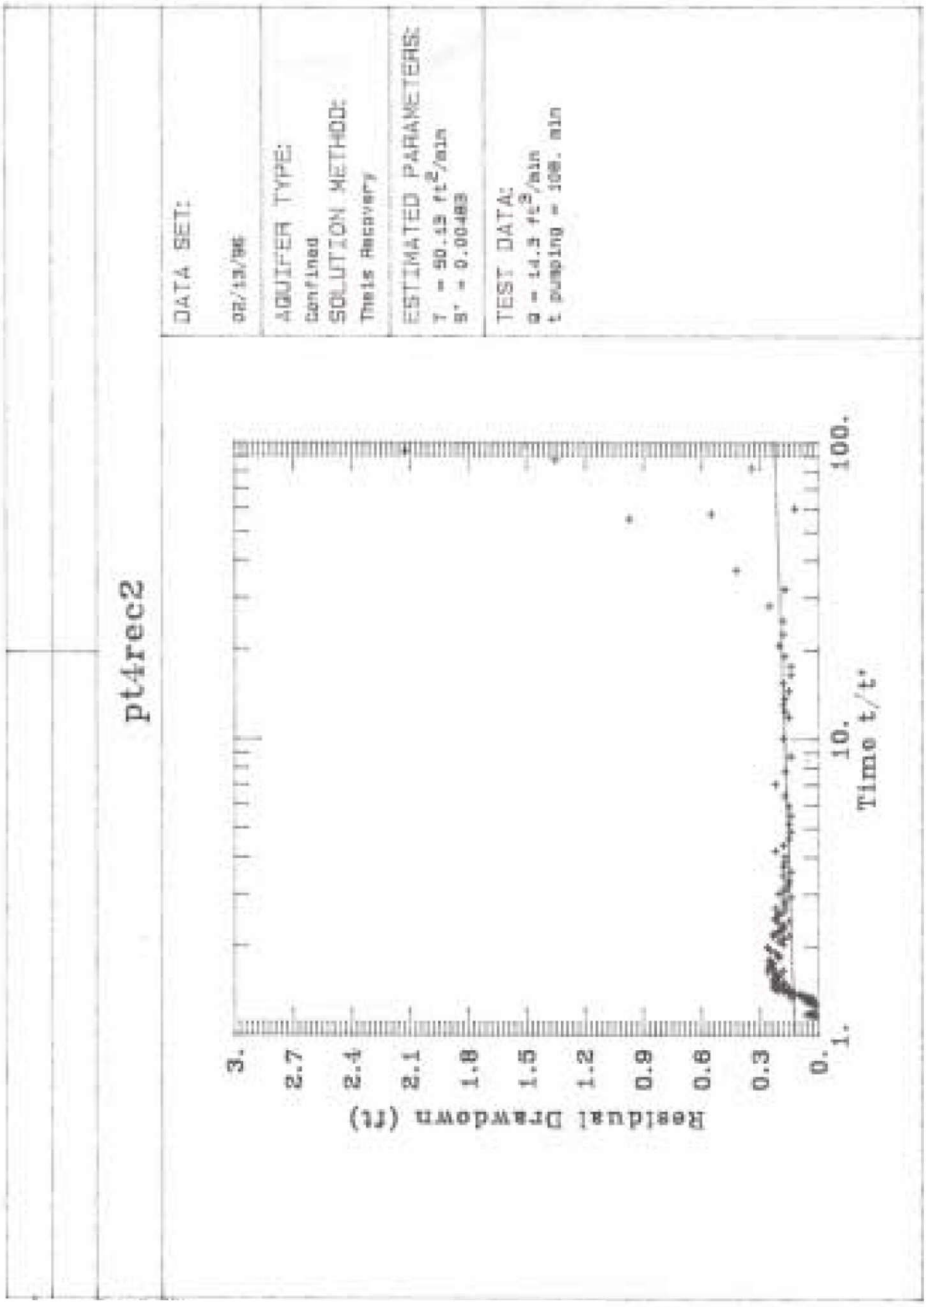

Figure C-4. Packer Test Recovery Data (Packer Test 4).

APPENDIX D - AQUIFER PERFORMANCE TEST DATA AND ANALYSES

AQUIFER PERFORMANCE TEST #1

1,050 - 1,252 feet

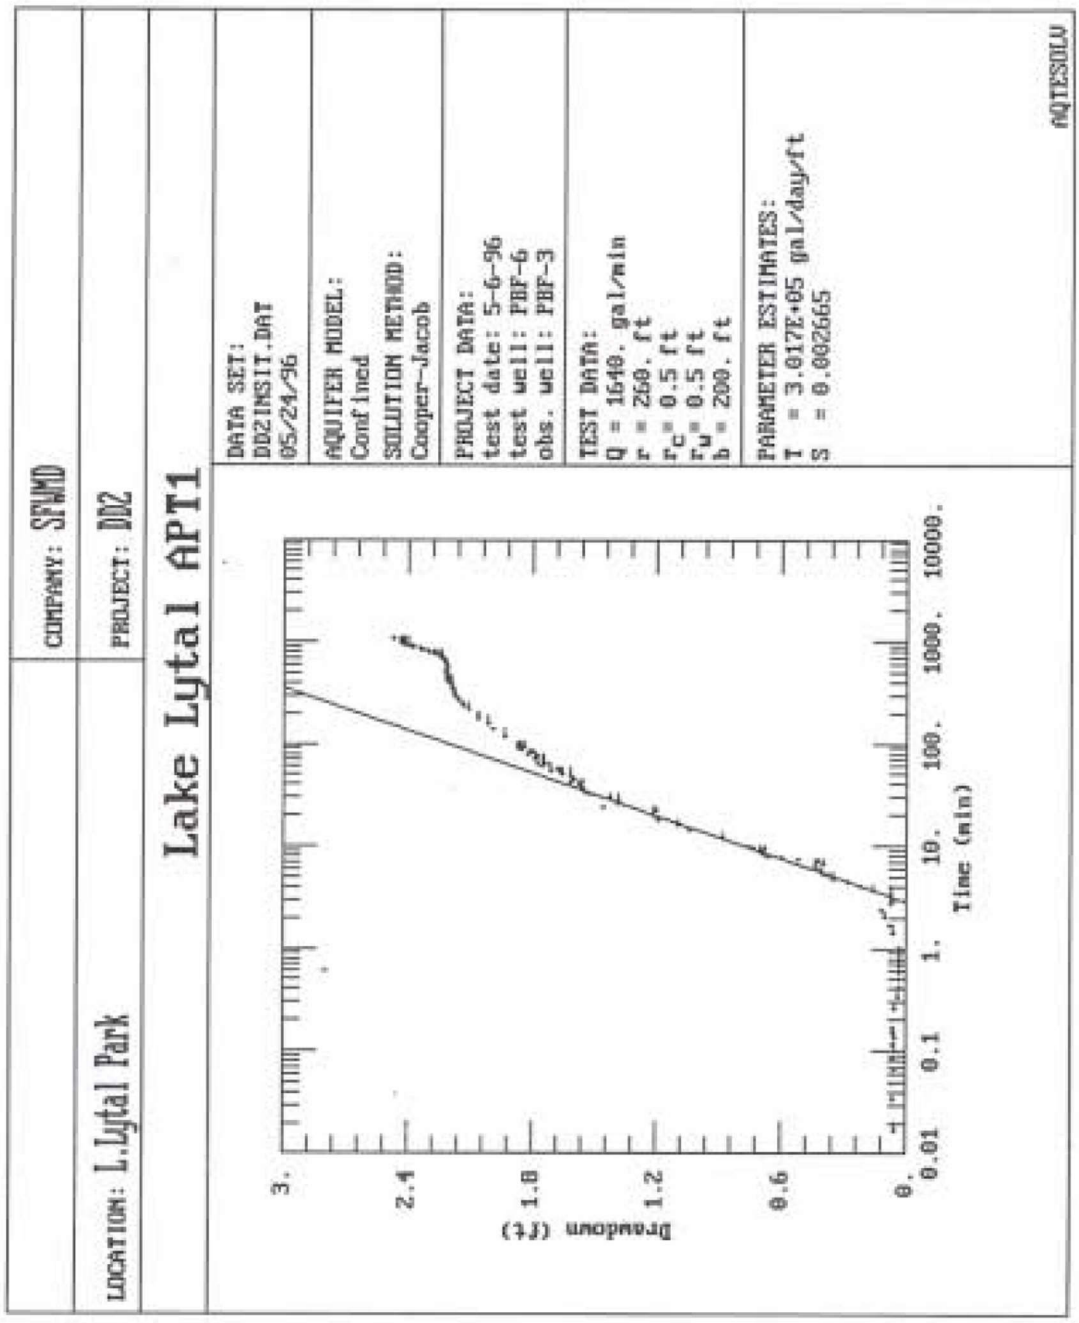

Figure D-1. APT No. 1 Drawdown Data (Cooper-Jacob Analysis).

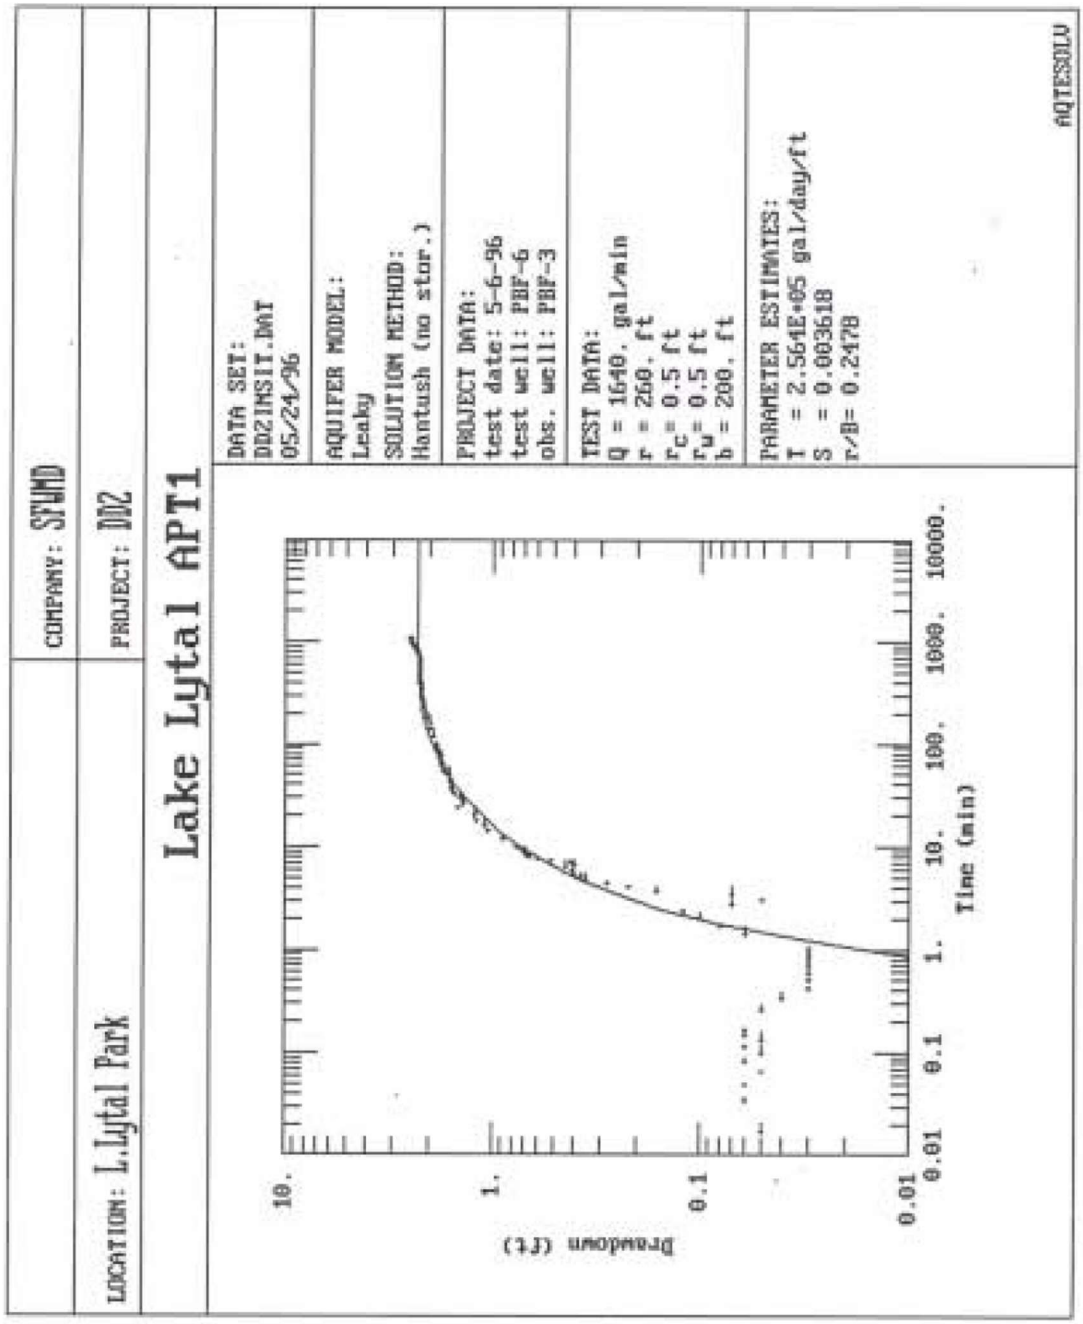

Figure D-2. APT No. 1 Drawdown Data (Hantush Analysis).

AQUIFER PERFORMANCE TEST #2

1,360 - 1,510 feet

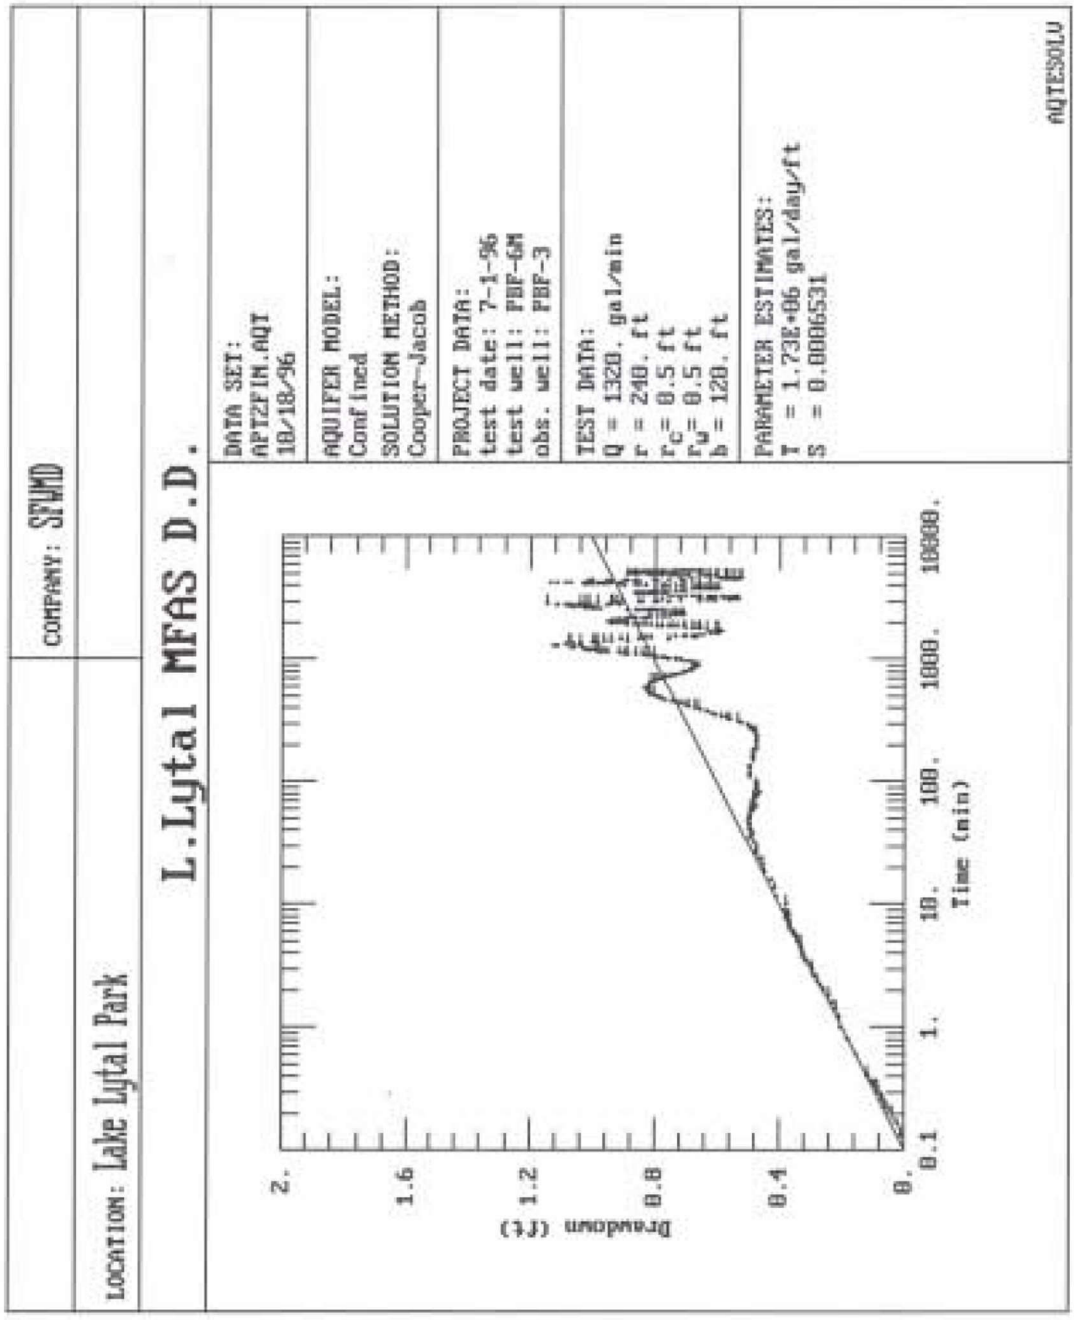

Figure D-3. APT No. 2 Drawdown Data (Cooper-Jacob Analysis).

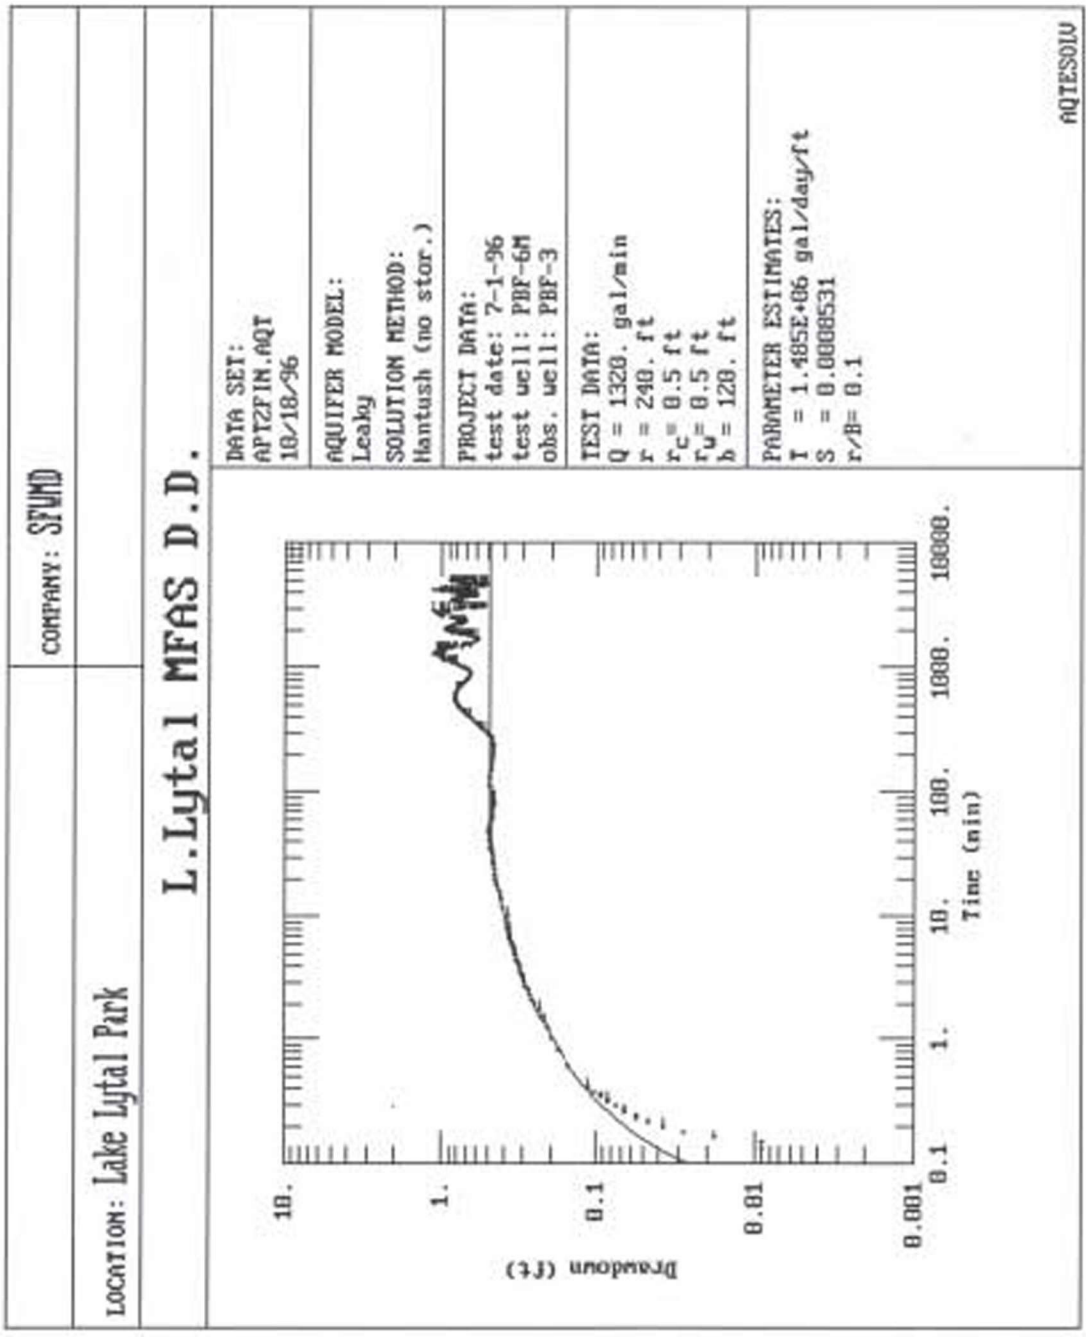

Figure D-4. APT No. 2 Drawdown Data (Hantush Analysis).

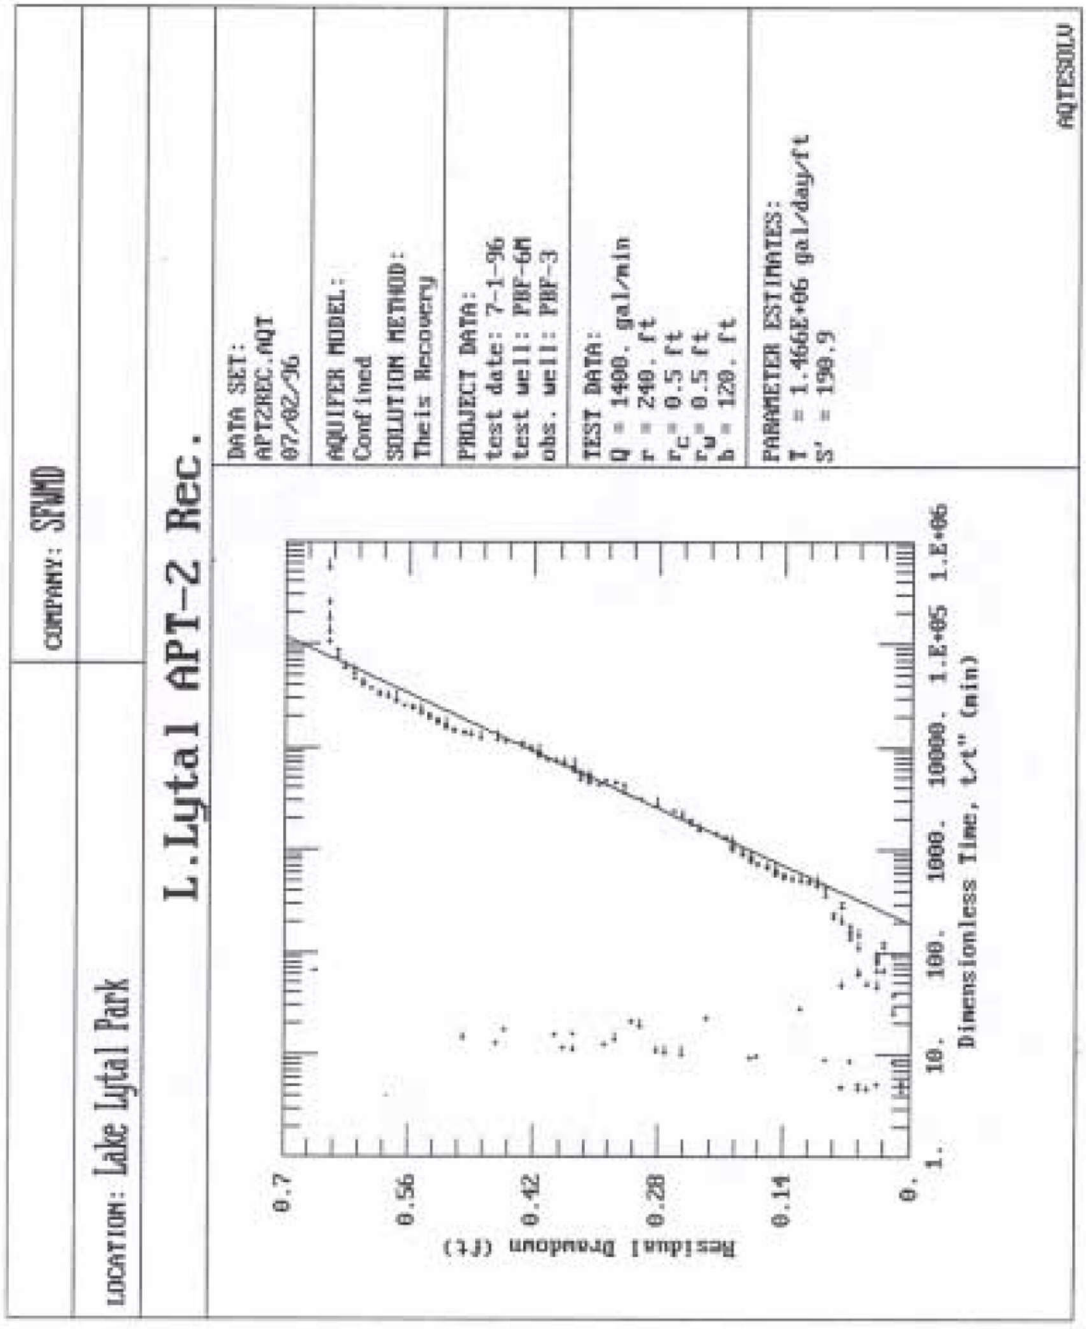

Figure D-5. APT No. 2 Recovery Data (Theis Recovery Analysis).
