ABSTRACT

Keywords: landscape position, soils, SSURGO, GIS

An updated single soil database of soil map units in South Florida, based on groups of similar morphologic characteristics, has improved the ability to visualize the spatial patterns of soils and to extract quantitative data for modeling and other hydrologic analyses. Soil characteristics reflect the complex interaction among topography, climate, vegetation, hydrology, and parent material. In South Florida, very small changes in topography can greatly affect hydrologic response. Soil survey maps compiled by the Natural Resources Conservation Service (NRCS) contain a wealth of spatial and analytical data but have been difficult to apply because of the large size, use of different names, and complexity of the database for each county.

As part of a previous cooperative effort by NRCS and staff at the South Florida Water Management District, spatial layers of county-level soil surveys (Soil Survey Geographic Data Base, or SSURGO) were edgematched and corrected to create a seamless Geographic Information System (GIS) database. The overall database included detailed soils for 19 counties, containing 195,000 polygons, with 909 soil mapping units and 220 distinct soil types. A set of 34 data fields (such as slope, hydric, and surface texture) was developed and checked and corrected for each mapping unit and is identified in the Natural Soils Lnadscape Positions (NSLP) database. Three classifications of the soil database were conducted, categorizing the large soils database into a relatively small number of categories (12 or less). These three classifications are based on depth and duration of the seasonal high water table, ecological community types, and NSLP types. The NSLP is a more complex classification based on the depth of the seasonal high-water table, soil morphological characteristics, and geographical location. These parameters were used to define 10 natural landscape positions that are significant to South Florida (water, tidal, marl and rocky, Everglades peat, muck depressions, sand depression, flats, flatwoods, knolls, Central Ridge & Dunes, and urban or made lands). The initial criteria were adjusted and evaluated until a consistent and useful classification was obtained.

ACKNOWLEDGEMENTS

This project was a cooperative effort between the South Florida Water Management District (SFWMD) and the Natural Resources Conservation Service (formerly Soil Conservation Service). The SFWMD provided Geographical Information System (GIS), graphical, and planning support. Dale Woodruff provided technical assistance in analysis of the data base and map production. Steve Traver and Rick Miessau provided technical support on the creation the website. Ellen Negley and Debra Case provided graphical support for the production of the poster and some graphical aspects of this technical publication.

We would like to recognize the members of the Planning and Water Resource Evaluation Departments who converted the soils maps into digital form and updated and improved the SSURGO databases under SFWMD contract C-3119. Supporting staff includes Ed Biggs, Joe Chapa, Tim Scharff, Tim Liebermann, and Mike Rose. These coverages and databases form the foundation of the work described here.

This project has been funded in part by the United States Environmental Protection Agency (USEPA) under Assistance Agreement ID Number X9948864-96-0 to the South Florida Wetlands Conservation Strategy. The contents of this document do not necessarily reflect the views and policies of the USEPA, nor does mention of trade names or commercial product constitute endorsement or recommendation for use.

INTRODUCTION

The Soil Classification Database is a reclassification of county soil survey data published by the Natural Resources Conservation Service (NRCS), formerly the Soil Conservation Service (SCS). A total of 907 soil map units were sorted by similar hydrological, morphological, and vegetation characteristics. New classification fields resulting from this process were added to the database to allow the user to group soils data into categories based upon specific characteristics.

The purpose of developing these new classification fields was to bring the large digital county soil database into a single user-friendly database, and to provide a clearer understanding of the relationships that exist between soil, hydrology, and the vegetation community. The resulting data offers a simplified soil landscape layer within the South Florida Water Management District's (SFWMD) Geographical Information System (GIS) that contains 34 fields.

The Soil Classification Database provides modelers, planners, and resource managers with an interpretation of the natural landscape not available from existing sources. Because the soils data can be categorized by hydrological characteristics and relative topography, regional patterns of hydrology become more evident. Correlation of hydrological conditions to ecological communities allows the soils data to be used to visualize the extent of certain habitats. This database can also be useful in determining the historical and present day areal extent of wetlands.

This document describes each classification of the soils in separate sections. The appendices contain the data table used in these classifications and other reference materials associated with the database. Other products resulting from this project include a poster (see foldout in the back of this document), a CD-ROM that contains the database, and a website (http://www.sfwmd.gov/org/pld/proj/wetcons/nslp/nslp_home.html). Each of these supplemental products are designed to distribute the data, map layer, and other information about this project to a wide audience of users.

The Soils Classification Database does not improve the accuracy, reliability, or quality of the soils data; the method presented here seeks only to improve the usability of the data. Please refer to the section entitled "Use of the Soils Classifications" before applying any classifications outlined in this publication.

GENERAL METHODS

As a base map layer, we used the seamless GIS coverage of the digital Soil Survey Geographic Data Base (SSURGO) for 16 counties within the boundaries of the SFWMD. This map layer was created as part of a previous cooperative effort between the SFWMD and the NRCS (contract #C-7271). Three additional counties (Indian River, Hardee, and DeSoto) which lie along the SFWMD boundary were included in the study area (**Figure 1**). Thirty-five data fields from the SSURGO Component (COMP) table and the Field Office Technical Guide (FOTG) table (SCS, 1992) for these 19 counties were combined into a single database. A list of the fields available in the Soil Classification database with the respective type and origin of the data are presented in Appendix E. The database was then modified so that only the largest soil component (SEQNUM 1 in SSURGO COMP table) of the map unit (MUID) was retained.

The edited database was then verified item-by-item across all data fields to search for errors and to update older soil data to values currently defined by the NRCS. These updates included a change from alphabetic to numeric identifiers for soils map units and a revision of the range for the seasonal high water table (SHWT) for a few flatwood soils.

The database was sorted for a number of value ranges for different characteristics, which were used to create new classification categories. The classification schemes are: 1) depth and duration of the SHWT, 2) ecological community types, and 3) NSLP type, which includes hydrological, morphological, and geographical considerations. The category ranges for these classifications are described in the following sections. The total area in each classification category were calculated (for county and study area) and are presented in the Appendices. Maps were created for each of the respective classification schemes by sorting on the respective category field, GIS software was then utilized to generate a map layer from the spatial database.

CLASSIFICATION BY DEPTH AND DURATION OF THE SHWT

This classification is based on the depth (relative to the soil surface) and persistence of the SHWT in an average year. The category designations use a multi-level numerical coding similar to the Florida Land Use Coding Classification System (SFWMD, 1994). Generally, the range of values for the depth to the SHWT, as defined for each map unit in SSURGO, were sequentially classified into eight groups (one group for "no data" is included). Each group contains the map units that have a SHWT depth and duration within a specified range. For example, one group contains all map units that have a SHWT above the soil surface. Another group contains all map units that have the upper range of the SHWT at the soil surface. These groups were arranged along a gradient of values and designated Level 1 category codes (100, 200, 300, etc.). Lower numbers indicate drier/shorter hydrology. Subgroups of SHWT values within each Level 1 category are designated by a Level 2 code (10, 20, 30, etc.). The Level 2 codes are the

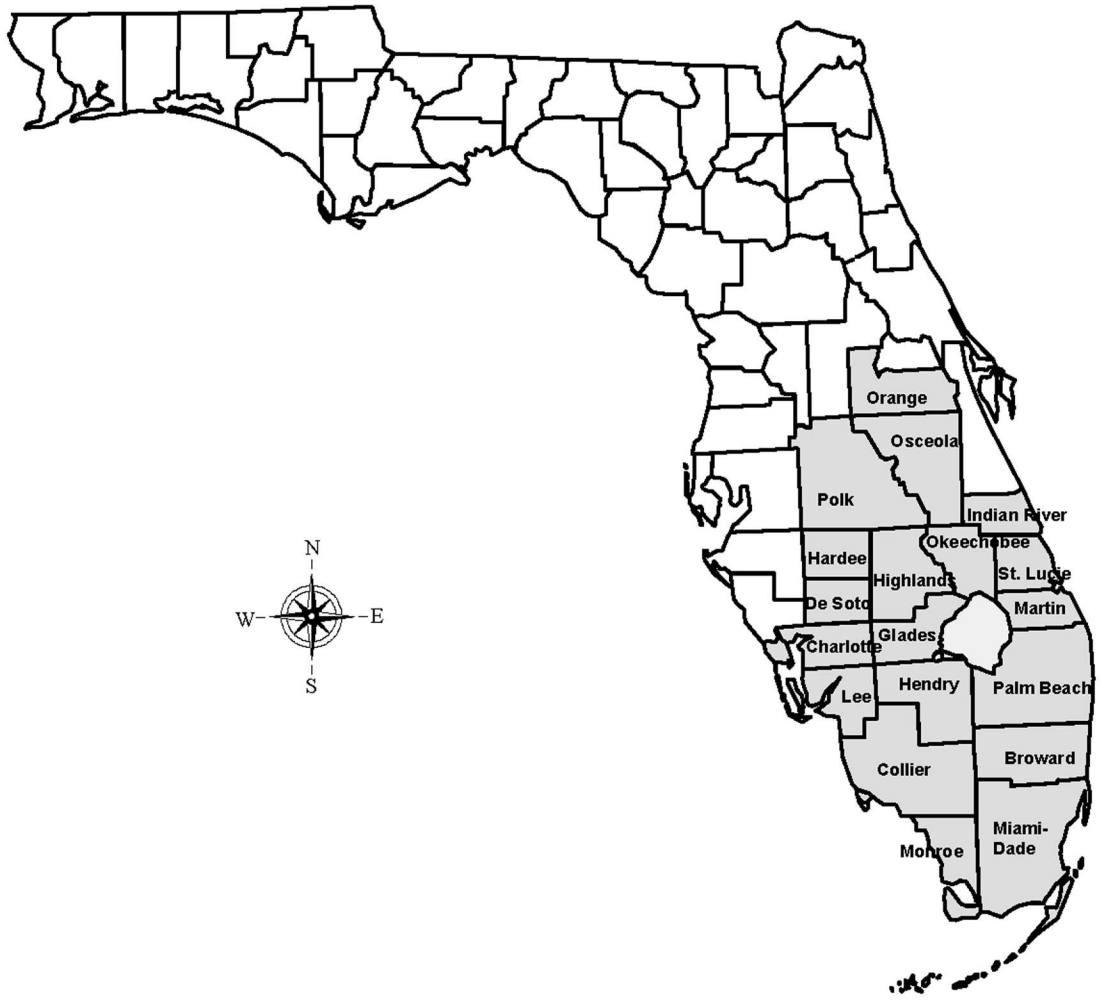

Figure 1. Map Extent of the Soils Classification Database, Indicated by the Shaded Counties.

actual map unit ranges for the SHWT and were also assigned to reflect a gradient of values (i.e., 510 = 1.0 to 1.5 ft. below the soil surface; 520 = 1.0 ft. below the soil surface; 530 = 0.5 to 1.5 ft. below the soil surface; and 540 = 0.5 to 1.0 ft. below the soil surface). Because SHWT ranges are inconsistent between map units, the ranges at Level 2 are not mutually exclusive and overlap between classes. Level 3 codes (1, 2, 3, etc.) indicate the duration of the SHWT and is expressed as the number of months minus three. Level 1, Level 2, and Level 3 codes are given as separate fields ("SHWT-L1", "SHWT-L2", and "SHWT-L3", respectively) in the database. **Table 1** contains a general description of the category codes used in this classification. Please refer to Appendix A for a complete listing of category codes and related SHWT ranges.

Table 1. Classification Codes Used to Classify Soils by Depth and Duration of the SHWT.

Classification Level	Level Code	Description
Level 1: Main Categories	100 200 300 400 500 600 700 800 900	SHWT deep, from 2 to more than 6 ft. below the soil surface. Beaches, saltwater table from 0 to 6 ft. below the soil surface. SHWT varies widely, from 0 to 6 ft. below the soil surface. SHWT ranges1.0 to 4.0 ft. below the soil surface. SHWT ranges 0.5 to 1.5 ft. below the soil surface. SHWT-H at the soil surface. SHWT-H above soil surface. Water areas. No data available.
Level 2: Category Subgroups	10, 20, 30, 40, 50, 60, 70	Map unit SHWT ranges within a category
Level 3: SHWT Duration	0 through 9	SHWT duration (code no. is equal to the duration of months minus 3).

This classification method was developed to give the user a means to map local topography and hydrology, based on the location of the SHWT in an average year under natural conditions. Specifically, this method can also be useful in determining hydrological patterns and the course of major flow ways within the landscape. Category codes have been assigned to reflect a hydrological gradient. Lower category code numbers indicate a drier hydrological regime with respect to duration of the SHWT, depth to the SHWT, or duration of flooding or ponding of water on the soil surface. For instance, in an average year under natural conditions, a category 713 map unit has a shorter hydroperiod than a 719 map unit, since the latter has a SHWT that lasts 6 months longer. Similarly, a category 134 map unit lies higher in the landscape (i.e., has a greater depth to the SHWT) than a 713 map unit. A map was created using the Level 1 field data (**Figure 2**). It is important to remember that soil conditions are predictable over periods of time, but they are not predictable from year to year. For example, soil scientists can predict with a fairly high degree of accuracy that a given soil will have a high water table within certain depths in most years, but they cannot assure that a high water table will always be at a specific level in the soil on a specific date (NRCS, 1998).

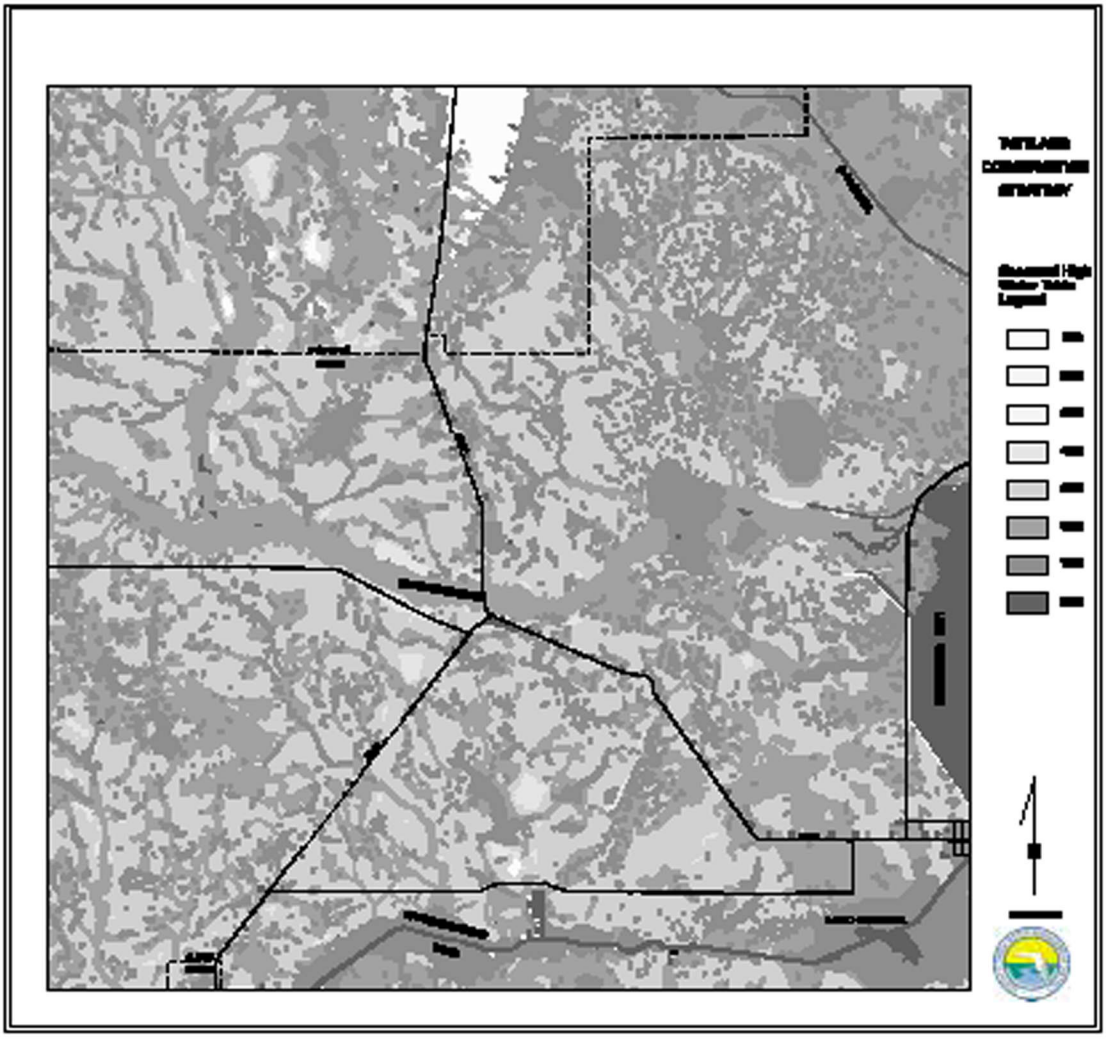

Figure 2. Map of the Level 1 SHWT Categories for a Sample Area on the West Side of Lake Okeechobeee.

Level 1: 100

In these areas, the SHWT has a depth ranging from 2 to more than 6 ft. below the soil surface for most of the year. Flooding never occurs and the soils usually consist of deep sandy marine deposits mostly found in the highlands of Central Florida or along ancient coastal dunes or strands. For this reason, these sites are under heavy development pressure. Dominant vegetation can include pines, scrubby oaks, rosemary (*Ceratiola ericoides*), lichens, and cactus (*Opuntia* spp.). Fire plays a crucial role in determining the dominant vegetative components of these communities. The ecological communities (SCS, 1989) included in this category are the Sand Scrub and the Longleaf Pine-Turkey Oak Hills. Please refer to Appendix D for a detailed description of the Sand Scrub Ecological Community.

Level 1: 200

This category contains beaches, which have a saltwater table that ranges from 0 to 6 ft. below the soil surface. Variation of the water table is usually daily due to tidal action, however much larger extremes can occur during storm events. These areas include sand and shell beaches along both the Atlantic and Gulf coasts and beach foredune communities that develop on the unconsolidated deposits. Typical animals include beach mice, gulls, terns, shorebirds, sea turtles, and crabs. Typical plants include sea oats (*Uniola paniculata*) and other grasses, railroad vine (*Ipomoea pes-caprae*), seagrape (*Coccoloba uvifera*), scrub oaks (*Quercus* spp.), and Spanish bayonet (*Yucca aloeifolia*). Usually, all species are salt tolerant and tall woody vegetation is wind sculpted due to exposure to sea spray.

Level 1: 300

This category contains areas that have a highly variable SHWT. These sites have a freshwater table that varies from 0 to 6 ft. below the soil surface, mostly due to frequent flooding conditions. Vegetation can also vary with these sites, depending on local conditions and duration of soil saturation over the past several years. Fire can play a crucial role in determining the dominant vegetative components of these communities.

Level 1: 400

This category contains sites that have a SHWT that ranges from 1.0 to 4.0 ft. below the soil surface. Some of these areas may rarely flood. Plant communites found on these sites can vary, depending on the duration of the SHWT relative to the soil surface. Drier sites may support some xeric vegetation or scrubby flatwoods. Wetter sites may support pine flatwoods, dry prairies, or low hammocks. Fire plays a crucial role in determining the dominant vegetative components of these communities.

Level 1: 500

This category contains sites that have a SHWT that ranges from 0.5 to 1.5 ft. below the soil surface. Flooding may occur frequently or occasionally in wetter years. These sites are most often dominated by pine or palm flatwoods, dry prairies, or low hammocks. Generally, flatwoods are characterized by a relatively open overstory of pines, an extensive low shrub stratum, and a variable herbaceous layer. Each of these components show xerophytic and pyrophytic physiognomy (Harper, 1914; Gunter, 1921; Laessle, 1942; Edmisten, 1963; Abrahamson and Hartnett, 1990). Pine canopy density can vary widely, from dense to very widely scattered. Slash pine is the dominant overstory flatwoods species in South Florida. The ecological communities (SCS, 1989) included in this category are South Florida Flatwoods, Everglades Flatwoods, and Cabbage Palm Flatwoods. For a detailed description of the South Florida Flatwoods Ecological Community, please see Appendix D.

Level 1: 600

This category contains sites that have a SHWT-High range at the soil surface. Flooding may frequently occur. These sites are mostly dominated by hydrophytic vegetation, either halophytic or halophobic. Mangrove swamps and salt marshes are found in saltwater areas of low to zero wave energy, such as along the coastline of the southern peninsula (e.g., the Ten Thousand Islands, Whitewater Bay, Florida Bay, and southern Biscayne Bay). Red mangrove (*Rhizophora mangle*), black mangrove (*Avicennia germinans*), and white mangrove (*Laguncularia racemosa*) are important tree species of the mangrove swamps. Tidal flat communities (e.g., oyster bars, seagrass beds) can be found along shallow tidal creeks, lagoons, or along the Intracoastal Waterway. Intra-tidal wetlands provide valuable habitat for a wide range of invertebrates, fishes, amphibians, reptiles, birds, and mammals (Odum and McIvor, 1990). A review of the literature by Odum et al. (1982) reported some 220 species of fish, 24 species of reptiles and amphibians, 18 species of mammals, and 181 species of birds depend on mangrove habitat. Please refer to Appendix D for more a detailed description of the Salt Marsh Ecological Community.

Freshwater marshes are nonforested wetlands of open expanses of grasses, sedges, and/or rushes. Wet prairies are the least flooded of any Florida marsh type (Kushlan, 1990). Species composition varies as a function of hydroperiod, soil type, fire frequency, and site history. Because of the shorter hydroperiods, wet prairies are species-rich and include a variety of grasses, sedges, and flowering forbes. Wetter sites may contain sawgrass and saw palmetto (*Serenoa repens*) and may invade drier sites. Ecological communities in this category are the Cutthroat Seeps and Sloughs (wet prairies). More detailed descriptions of the Sawgrass and Sloughs (wet prairie) Ecological Community can be found in Appendix D.

Level 1: 700

This category contains sites that have a SHWT-High range above soil surface. These sites support wetland vegetation. Freshwater marshes and ponds are nonforested wetlands of open expanses of grasses, sedges, and/or rushes. Occasional open-water areas may be present, often inhabited by water lily (*Nymphaea odorata*), spadderdock (*Nuphar luteum*), bladderworts (*Utricularia* spp.), or stoneworts (*Chara* spp.). A number of marsh types are recognized, each based upon the dominant species. These include arrowhead (*Sagittaria* spp.) marshes, sawgrass (*Cladium jamaicense*) marshes, fire flag (*Thalia geniculata*) marshes, bulrush (*Scirpus* spp.) marshes, spike-rush (*Eleocharis* spp.) marshes, cattail (*Typha* spp.) marshes, and maidencane (*Panicum hemitomon*) marshes. More detailed descriptions of the Sawgrass Ecological Community and the Freshwater Marsh Ecological Community can be found in Appendix D.

Level 1: 800

Water areas are sites that are inundated by 2 ft. of water or more throughout the year. These sites usually support aquatic vegetation. A variety of aquatic communities can be found in open water bodies, each of which is a function of the history and characteristics of the site. For instance, borrow pits may have sparse plant or animal communities if they are remote from wetlands or other water bodies. Stagnant freshwater lakes or those that have somewhat elevated nutrient levels (e.g., from agricultural or urban runoff) may contain floating plants (e.g., *Eichhornia crassipes, Pistia stratiotes*), filamentous green algae (e.g., *Spirogyra* spp.), scuds (*Hyalella azteca*), seed shrimp (Ostracods), and water fleas (*Daphnia* spp.). Freshwater lakes with high water quality can host a variety of plants and animals, such as bladderworts (*Utricularia* spp.), calcareous algae mats, freshwater sponges (e.g., *Spongilla lacustris*), pupfish (*Jordanella floridae*), livebearers (e.g., *Gambusia affinis*, *Heterandria formosa*), and sunfish (e.g., *Lepomis* spp.).

Level 1: 900

No data is available for these sites because of resource limitations or inaccessiblity. Some private land owners denied soil survey staff access to thier property. Public lands were not mappped unless the managing agency was willing to fund.

CLASSIFICATION BY ECOLOGICAL COMMUNITY TYPE

This classification is base upon the ecological communities (defined by the NRCS) associated with map unit components in the SSURGO database. During the soil survey mapping process a soil series was taxonomically defined and a number of attributes were assigned to it, such as range of pH values, hydrological group, and ecological community present. The ecological community presented in the FOTG database for a given soil map unit component is that which was present when and where the map unit was defined. However, if a map unit component was defined in a coastal area in the mid-1970's, it is

quite possible that the ecological community present today is different because of hydrological changes, nonnative vegetation invasions, or fire suppression. Furthermore, occurrences of that map unit much farther inland may have a different ecological community, especially where there is a climatic gradient. This is often the case in central-south Florida were tropical vegetation tends to be restricted to coastal areas.

Because of these difficulties, accurately assigning specific ecological communities to a soil map unit component that is regionally distributed can lead to considerable imprecision. For this reason, this generalized classification was derived to offer the soils database user a more accurate definition of what biological community types can be expected on a given soil. Biological communities are grouped into categories based on similarities of characteristics, such as saltwater wetlands, freshwater wetlands, flatwoods, uplands, etc. One category is included for mapping units that have no ecological data available. **Table 2** shows the different categories and a description of each used in this classification. A map created from these ecological community categories (ECC) is shown in **Figure 3**. Appendix B contains the full description of the categories and specific ecological communities included within them.

Table 2. Ecological Community Category Definitions.

Category Number	Category Name	Category Description
1	Water	Aquatic communities, usually inundated to a depth of 2 ft. or more
2	Intra-tidal Wetlands	Coastal wetland communities; low wave energy coast line
3	Beaches	Beach communities; high wave energy coastlines
4	Freshwater Wetlands	Freshwater marshes and swamps
5	Swamp Hammock	Forested mesic communities, usually transitional
6	Wet Prairie	Short-period wetlands. Generally treeless and grass-dominated
7	Flatwoods	Usually pine and/or palm-dominated flatwood communities
8	Uplands	Upland forested communities that seldom flood
9	Highlands	Scrub and xeric communities, usually pine and oak dominated
10	N/A	No data available

ECC #1 Water

The water category denotes areas that were described as open water bodies in the county soil surveys. These sites are permanently inundated, usually to a depth of two feet or greater. This includes freshwater, saltwater, natural, and excavated sites. However, a variety of aquatic communities can be found in open water bodies, each of which is a function of the history and characteristics of the site. For instance, borrow pits may have sparse plant or animal communities if they are remote from wetlands or other water bodies. Stagnant freshwater lakes or those that have somewhat elevated nutrient levels (e.g., from agricultural or urban runoff) may contain floating plants (e.g., *Eichhornia crassipes, Pistia stratiotes*), filamentous green algae (e.g., *Spirogyra* spp.), scuds

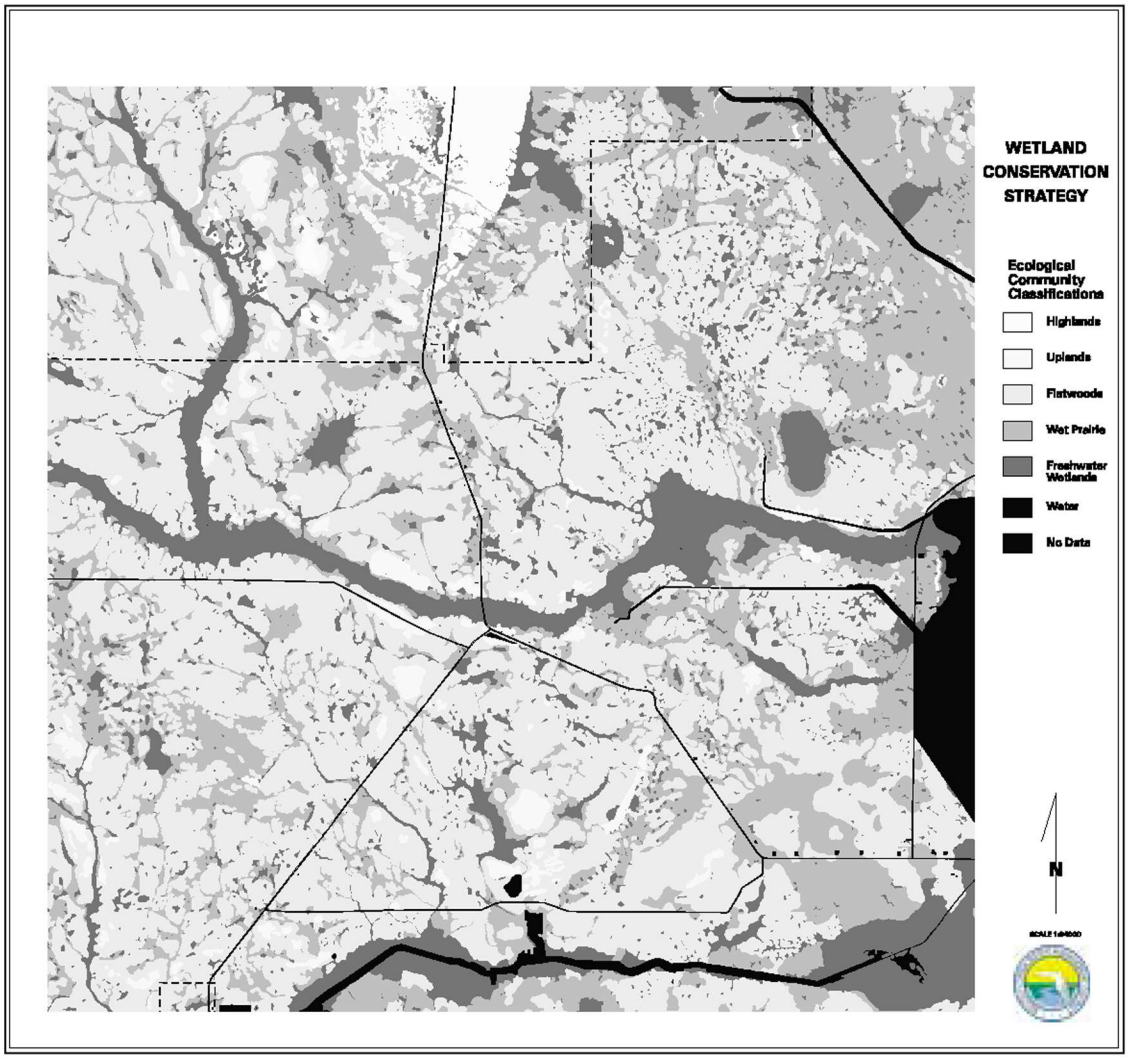

Figure 3. Map of the Ecological Community Categories for a Sample Area on the West Side of Lake Okeechobeee (beaches, intra-tidal wetlands, and swamp hammocks are omitted from this map, as they are not found in this area).

(*Hyalella azteca*), seed shrimp (Ostracods), and water fleas (*Daphnia* spp.). Freshwater lakes with high water quality can host a variety of plants and animals, such as bladderworts (*Utricularia* spp.), calcareous algae mats, freshwater sponges (e.g., *Spongilla lacustris*), pupfish (*Jordanella floridae*), livebearers (e.g., *Gambusia affinis*, *Heterandria formosa*), and sunfish (e.g., *Lepomis* spp.).

ECC #2 Intra-Tidal Wetlands

Intra-tidal wetlands are saltwater marshes and swamps that are subject to regular tidal flooding. Mangrove swamps and salt marshes are found in areas of low to zero wave energy, such as along the coastline of the southern peninsula (e.g., the Ten Thousand Islands, Whitewater Bay, Florida Bay, and southern Biscayne Bay). Red mangrove (*Rhizophora mangle*), black mangrove (*Avicennia germinans*), and white mangrove (*Laguncularia racemosa*) are important tree species of the mangrove swamps. Tidal flat communities (e.g., oyster bars, seagrass beds) can be found along shallow tidal creeks, lagoons, or along the Intracoastal Waterway. Beach formation is negligible, allowing the substrate to be stabilized by vegetation. Halophytic species typically predominate. Intra-tidal wetlands provide valuable habitat for a wide range of invertebrates, fishes, amphibians, reptiles, birds, and mammals (Odum and McIvor, 1990). A review of the literature by Odum et al. (1982) reported some 220 species of fish, 24 species of reptiles and amphibians, 18 species of mammals, and 181 species of birds depend on mangrove habitat. Please refer to Appendix D for more a detailed description of the Salt Marsh Ecological Community.

Soils in these wetlands are usually Aquents (an Entisol) or Aquods (a Histosol), and are hydric. They are nearly level, very poorly to poorly drained soils of variable-textured mineral and organic materials subject to frequent tidal flooding. The water table, which is typically saltwater, can range from the soil surface to one foot above the surface throughout the year.

ECC #3 Beaches

Beach communities are found in areas where sand deposition or wave energy is high. Dunes are built up as vegetation increase the surface roughness, causing the wind to slow and to drop sand grains being moved across the beach (Barbour et al., 1987; Bagnold 1941). The highly variable, typically salt water table, can range from the soil surface to six feet below the surface. This includes sand and shell beaches along both the Atlantic and Gulf coasts and dune communities that develop on the unconsolidated deposits. Typical animals include beach mice, gulls, terns, shorebirds, sea turtles, and crabs. Plants include sea oats (*Uniola paniculata*) and other grasses, railroad vine (*Ipomoea pes-caprae*), seagrape (Coccoloba uvifera), scrub oaks (*Quercus* spp.), and Spanish bayonet (*Yucca aloeifolia*). Usually, all species are salt tolerant and tall woody vegetation is wind sculpted due to exposure to sea spray. As with intra-tidal wetlands, these communities play an important role in shoreline stabilization and preventing erosion of the coast during storms.

ECC #4 Freshwater Wetlands

Freshwater wetlands can be either forested and nonforested. These can be roughly divided into three kinds: freshwater marshes, baldcypress swamps, and hardwood swamps. Freshwater wetlands can be found on a wide range of soils types and usually are inundated for at least a portion of the year. The SHWT can vary from two feet above to one foot below the soil surface for four or more months during the year. Occasional open-water areas may be present, often inhabited by water lily (*Nymphaea odorata*), spadderdock (*Nuphar luteum*), bladderworts (*Utricularia* spp.), or stoneworts (*Chara* spp.).

Marshes are treeless wetlands usually compose of sedges or other emergent plants. A number of marsh types are recognized, each based upon the dominant species. These include arrowhead (*Sagittaria* spp.) marshes, sawgrass (*Cladium jamaicense*) marshes, fire flag (*Thalia geniculata*) marshes, bulrush (*Scirpus* spp.) marshes, spike-rush (*Eleocharis* spp.) marshes, cattail (*Typha* spp.) marshes, and maidencane (*Panicum hemitomon*) marshes.

Cypress swamps inhabit the frequently flooded rock and marl soils of southern Florida, floodplains, seasonally flooded basins, and depressional areas. Typical species include bald cypress (*Taxodium distichum*), pond cypress (*Taxodium distichum* var. *ascendens*), willow (*Salix caroliniana*), wax myrtle (*Myrica cerifera*), red maple (*Acer rubrum*), dahoon (*Ilex cassine*), buttonbush (*Cephalanthus occidentalis*), sawgrass, and airplants (mostly *Tillandsia* spp.). Often these swamps are used as nesting sites for a number of birds and other wildlife. Included in this category are the Scrub Cypress Ecological Community and the Cypress Swamp Ecological Community. More detailed descriptions of both of these ecological communities can be found in Appendix D.

Hardwood swamps include all hardwood-dominated freshwater wetland forests. Bays, pop ash (*Fraxinus caroliniana*), red maple, cabbage palm (*Sable palmetto*), dahoon, and laurel oak (*Quercus laurifolia*) are usual components. Baldcypress and pond cypress may be present, but only occasionaly. The community can have an evergreen appearance since it can be dominated by laurel and water oaks, cabbage palm, and bays. Ferns and other shade tolerant herbaceous plants are common. These wetlands are important to a number of wildlife species. Owls, hawks, woodpeckers, ducks, and a variety of songbirds use these swamps as nesting and feeding sites. Black bear, raccoons, bobcat, deer, mink, and otter can also be found. These communities can be along rivers, streams, poorly defined drainage ways, depressions, and areas subject to constant seepage. The soils are very poorly drained and subject to high water tables.

ECC #5 Swamp Hammock

Swamp hammocks include forested mesic wetlands that are usually transitional areas. These seldom, if ever, are invaded by fires. Dominant overstory vegetation includes oaks, cabbage palms, occasional hardwoods (such as red maple), abundant ferns, and other herbaceous plants. These sites are occasionally flooded and have hydric soils.

Although these wetlands have a shorter hydroperiod than hardwood swamps, they contain a number of species in common with them.

ECC #6 Wet Prairie

Wet prairies are the least flooded of any Florida marsh type (Kushlan, 1990). Species composition varies as a function of hydroperiod, soil type, fire frequency, and site history. Because of the shorter hydroperiods, wet prairies are species-rich and include a variety of grasses, sedges, and flowering forbes. Wetter sites may contain sawgrass and saw palmetto (*Serenoa repens*) will invade drier sites. The SHWT generally ranges from the soil surface to one foot below the surface for four to nine months of the year. Ecological communities in this category are the Cutthroat Seeps and Sloughs (wet prairies). Please see Appendix D for a detailed description of the Sloughs Ecological Community.

ECC #7 Flatwoods

Flatwoods are characterized by low, flat topography, and relatively poorly drained, acidic, sandy soil typically underlain by an spodic horizon. This is the most extensive type of terrestrial ecosystem in Florida. The SHWT is typically just below the soil surface, except during periods of flooding. The term flatwood includes several vegetationally distinct communities found on a variety of soil types (Laessle, 1942). Generally, flatwoods are characterized by a relatively open overstory of pines, an extensive low shrub stratum, and a variable herbaceous layer. Each of these components show xerophytic and pyrophytic physiognomy (Harper, 1914; Gunter, 1921; Laessle, 1942; Edmisten, 1963; Abrahamson and Hartnett, 1990). Pine canopy density can vary widely, from dense to very widely scattered. Slash pine is the typical dominant overstory flatwoods species in South Florida.

There are other biological community types that can result from pine flatwoods, depending on the conditions of the site. Over-burned flatwoods may lack pines altogether. These are referred to as "dry prairies" and are usually dominated by saw palmetto. Flatwoods that have had fire suppressed for many years will develop into a "low hammock", dominated by oaks and palms. The ecological communities (NRCS, 1989) included in this category are South Florida Flatwoods, Everglades Flatwoods and Cabbage Palm Flatwoods. For a detailed description of the South Florida Flatwoods Ecological Community, please see Appendix D.

ECC #8 Uplands

The uplands category includes areas that flood as rarely as flatwoods do, but are too wet to support scrub vegetation. These communities support upland hardwood and tropical species (in the southern counties); a few pines may be present.

Uplands may be dominated by pines, hardwood forests, or grasslands, depending on local conditions. Frequent fires will result in pasture-like savanna, whereas fire

suppression will allow development of pine and oak forests. These sites seldom, if ever, flood and the water table is well below the surface most of the year.

Tropical hammocks generally appear as thick stands with a dense canopy cover. Soils may be thin with only a few inches of organic matter. Typical vegetation includes wild tamarind (*Lysiloma latisiliqua*), Jamaica dogwood (*Piscidia piscipula*), mastic (*Masticodendron foetidissimum*), poisonwood (*Metopium toxiferum*), strangler fig (*Ficus aurea*), wild coffees (*Psychotria* spp.), and marlberry (*Ardisia escallionoides*). Hammocks are good wildlife habitat for both resident and migratory birds. Many of the plant species produce fruit that are important food sources for wildlife. These habitats also provide cover for many mammals during periods of high water and resting sites for migratory birds.

ECC #9 Highlands

Highland communities are usually on elevated, well-drained sandy soils along the coast or in the interior highlands of Central Florida. Coastal Strand communities support a variety of tropical vegetation (South and Central Florida). Scrub communities support xeric species and are regarded as the most ancient biological communities found in Florida. They most often have a high number of endemic and endangered species. The SHWT is well below the soil surface and flooding rarely, if ever, occurs. For this reason, these sites are under heavy development pressure and are in a state of decline. Coastal Strand can be dominated by saw palmetto (*Serenoa repens*), sea grape (*Coccoloba uvifera*), and species originating from the Caribbean Basin. Dominant scrub vegetation includes pines, scrubby oaks, rosemary (*Ceratiola ericoides*), lichens, and cactus (*Opuntia* spp.). The ecological communities (see NRCS, 1989) included in this category are the Sand Scrub and the Longleaf Pine-Turkey Oak Hills. Please refer to Appendix D for a detailed description of the Sand Scrub Ecological Community.

ECC #10 No Data

This category includes map units that are urbanized, drained, or where no soil survey was conducted.

CLASSIFICATION BY NSLP TYPE

This classification is based on the landscape types found in South Florida, including flatwoods, Everglades, tidal areas, and urbanized areas. This classification includes consideration of the depth and duration of the SHWT, soil morphology, and the geographical location of the soil. This method of categorization of soils is referred to as the Natural Soils Landscape Position (NSLP) classification.

From the Soils Classification Database, we first selected all water body map units for water bodies, soils that are exposed to tidal flooding, and soils that have been disturbed (urbanized, excavated, or filled in). These were each assigned to separate categories.

Another category for areas of which no soil survey was conducted (no data) was also created. The remaining map units from the database were then sorted by range and duration of the SHWT, soil morphology, and geographic location. The specifics for these classifications are outlined in **Table 3**. Most map units were found inside the range of values for the landscape position definitions. However a few units lie just outside of the category range of values but have characteristics associated with them that necessitated their inclusion into a group. A map was created from the NSLP classifications and is presented in the pullout at the end of this document (**Figure 4**).

Table 3. Sorting Criteria for Soils Data by NSLP Type.

NSLP Type	General Sorting Criteria
#1 Water	Areas designated as "Water" in SSURGO
#2 Tidal Soils	Coastal soils that are subject to tidal influence, no freshwater table
#3 Marl & Rocky Soils	Transitional area between saltwater and freshwater zone in the southern Everglades, freshwater table dominates, and hydric marl or rocky soils
#4 Everglades Peat	Pure organic, hydric soils within the extent of the historic Everglades
#5 Muck Depressions	Depressional hydric soils with an organic surface layer over sandy sediments
#6 Sand Depressions	Depressional hydric soils composed of pure sands
#7 Flats Soils	Nondepressional hydric soils composed of pure sands
#8 Flatwood Soils	Nonhydric soils of pure sandy sediments, SHWT 0.5 to 1.5 ft. below soil surface four months annually
#9 Knolls	Nonhydric soils of pure sandy sediments, SHWT 1.5 to 6.0 ft. below soil surface less than 7 months annually
#10 Central Ridge & Dunes	Nonhydric soils of pure sandy sediments, SHWT 6 ft. or more below soils surface all year
#11 Urban or Made Lands	Excavated or built lands, original soil morphology disturbed
#12 No Data	No soil survey data available

NSLP #1 Water

The Water landscape position denotes areas that were described as open water bodies in the county soil surveys. Water areas are permanently inundated, usually to a depth of two feet or greater. This includes freshwater, saltwater, natural, and excavated sites. There are no soils data that are associated with the Water landscape position

A variety of aquatic communities can be found on this landscape position, each of which is a function of the history and characteristics of the site. For instance, borrow pits may have sparse plant or animal communities if they are remote from wetlands or other water bodies. Stagnant freshwater lakes or those that have somewhat elevated nutrient levels (e.g., from agricultural or urban runoff) may contain floating plants (e.g., *Eichhornia crassipes, Pistia stratiotes*), filamentous green algae (e.g., *Spirogyra* spp.), scuds (*Hyalella azteca*), seed shrimp (Ostracods), and water fleas (*Daphnia* spp.). Freshwater lakes with high water quality can host a variety of plants and animals, such as

bladderworts (*Utricularia* spp.), calcareous algae mats, freshwater sponges (e.g., *Spongilla lacustris*), pupfish (*Jordanella floridae*), livebearers (e.g., *Gambusia affinis*, *Heterandria formosa*), and sunfish (e.g., *Lepomis* spp.).

NSLP #2 Tidal Soils

Tidal soils are found along coastal areas in salt marshes, mangrove or tidal swamps, and areas adjacent to the Intracoastal Waterway that have tidal flooding influence. These soils are usually Aquents (an Entisol) or Aquods (a Histosol), and are hydric. These soils can be nearly level to sloping sandy beaches, or very poorly drained coastal marshes and swamps consisting of variable-textured mineral and organic materials, subject to frequent tidal flooding. The water table, which is typically saltwater, can range from one foot below to one foot above the soil surface throughout the year. Examples of these soils include Wulfert, Durbin, and Peckish.

This landscape position includes beaches that can have a hydrological range that is a much wider range than the category for the SHWT. Perrine Variant soils (silt loam and fine sandy loam) of Broward and Indian River counties are currently an exception to the rest of the soils in this category. These soils are found in low flats that may have an intermittent freshwater SHWT, lie adjacent to tidal areas along estuaries, support halophytic vegetation, and may occasionally be inundated by salt water during exceptionally high tides. Please refer to Appendix C for a detailed description of the range of values for map units in this category.

A number of diverse biological communities may be found on this landscape position, the type of which is mostly a function of the wave energy exposure of the site. Mangrove swamps and salt marshes can be found in areas of low to zero wave energy, such as along the coastline of the southern peninsula (e.g., the Ten Thousand Islands, Whitewater Bay, Florida Bay, and southern Biscayne Bay). Tidal flat communities (e.g., oyster bars, seagrass beds) can be found along shallow tidal creeks, lagoons, or along the Intracoastal Waterway. In areas where sand deposition or wave energy is high, beach or littoral communities tenaciously colonize the unstable substrate or rocky shoreline. Please refer to Appendix D for a more detailed description of the Salt Marsh, which is a common ecological community found on this landscape position.

NSLP #3 Marl & Rocky Soils

Marl and rocky soils occur in Miami-Dade, Monroe, and Collier counties along the southern extent of the Everglades. The Marl & Rocky Soils landscape denotes that area near the southern tip of the Florida peninsula adjacent to the tidal area of Florida Bay. Marl soils (mostly Aquents, an Entisol) are hydric and originate from the precipitation of calcite in the water by calcareous algae mats. Rocky soils have exposed limestone at or near the surface. These areas are poorly to very poorly drained. The seasonal high water table ranges from one foot below to one foot above the soil surface for four to seven months annually. Examples of these soil series include Biscayne, Perrine, and Rock Outcrops. Some areas are noted as drained phases which means that there has been

artificial drainage implemented, however the degree or effectiveness of the drainage is not expressed. Please refer to Appendix C for a detailed description of the range of values for map units in this category.

A number of biological communities may be found on this landscape position. Since this area includes the transition zone between saltwater and freshwater tables, but is dominated by the latter. Both salt and freshwater marsh vegetation can be found on this landscape position, sparse sawgrass marsh being a common type of the latter found in this area. Wet prairie (marl prairie) species composition varies greatly and depends on local conditions. These are often dominated by a variety of grasses, sedges, and flowering forbs. Muhly (*Muhlenbergia* spp.), maidencane (*Panicum hemitomon*), cordgrass (*Spartina* spp.), and beak rush (*Rhynchospora* spp.) are common dominant species (Kushlan, 1990). Other communities that may occur include tropical hammocks and scrub cypress. Scattered dwarf (scrub) cypresses are found on the thin, rocky soils along the southern extent of the Everglades. Please refer to Appendix D for a more detailed description of the Scrub Cypress ecological community.

NSLP #4 Everglades Peat

Everglades peat soils are very poorly drained organic hydric soils, usually derived from sawgrass (*Cladium jamaicense*), that have formed over the limestone bedrock. These soils are normally found within the geographic extent of the historic Everglades Basin. Examples of these soil series include Pahokee, Terra Ceia, and Lauderhill. Typically, these are pure organic soils with no significant sand layer deposit between the organic layer and the limestone bedrock. This category contains Histosols, which are morphologically distinguished from Muck Depressions (NSLP #5) and Sand Depressions (NSLP #6) although they may have similar hydrological conditions. The seasonal high water table can range from the soil surface to two feet above the surface for nine to eleven months annually. Please refer to Appendix C for a detailed description of the range of values for map units in this category.

The principle biological communities that may be found on this landscape position include dense sawgrass marsh and freshwater marsh. Please refer to Appendix D for a more detailed description of the Sawgrass Marsh ecological community.

NSLP #5 Muck Depression

Muck depression soils are very poorly drained hydric soils that have an organic surface layer underlain by sandy marine sediments. A few areas may have a thin organic surface layer only a few inches thick. This category includes the transitional area between the Everglades pure organic soils (NSLP #4) and the coastal sandy marine sediments. Often, Muck Depressions (NSLP #5) lie adjacent to Flats (NSLP #7) and Flatwood (NSLP #8) landscapes. The seasonal high water table typically ranges from one-half foot below to two feet above the soil surface for seven to eleven months annually. Examples of these soils include Hontoon, Kaliga, and Samsula. Also included within this unit are frequently flooded alluvial areas that have a muck surface for the majority of the area. These

frequently flooded map units may have a shorter SHWT duration, but are subject to frequent flooding during the wet season. Frequently flooded map units are known to have surface flooding at least one out of every two years. Please refer to Appendix C for a detailed description of the range of values for map units in this category.

Several biological communities may be found on this landscape position, including freshwater marsh, sawgrass marsh, bay heads, hardwood swamps, and cypress swamps. Local conditions favor one community over the other, with fire frequency and site hydrology playing large roles in their distribution. Please refer to Appendix D for more a detailed description of the Cypress Swamp ecological community.

NSLP #6 Sand Depression

The Sand Depression landscape position denotes all areas that have sandy marine sediments throughout the profile. A few areas may have mucky sand, loamy sand, or sandy loam surfaces with sandy or loamy subsurfaces. All of these soils are hydric. Often, these areas are depressions adjacent to Flats (NSLP #7) and Flatwood (NSLP #8) landscapes. These soils are very poorly drained and the seasonal high water table can typically range from one foot below to two feet above the soil surface for seven to ten months annually. Examples of these soil series include Basinger, Boca, and Riviera. Also included within this unit are frequently flooded alluvial soils that have a sandy surface for the majority of the area. These frequently flooded map units have a shorter duration for the SHWT, but are subject to frequent flooding during the wet season. Frequently flooded map units are known to have surface flooding at least one out of every two years. Please refer to Appendix C for a detailed description of the range of values for map units in this category.

Several biological communities that may be found on this landscape position, including freshwater marsh, sawgrass marsh, hardwood swamps, wetland hardwood hammocks, and cypress swamp. Local conditions favor one community over the other with fire frequency and site hydrology playing large roles in their distribution. Generally, sites that burn less frequently tend to support swamp forests, whereas more frequently burned sites tend to support marsh vegetation. Please refer to Appendix D for a detailed description of Freshwater Marsh and Ponds ecological communities.

NSLP #7 Flats Soils

Flats (referred to as "sloughs" by the NRCS) soils are poorly drained hydric soils with sandy marine sediments throughout the profile, or more rarely with loamy sand or sandy loam. Flats are located between the Flatwood (NSLP #8) and depressional landscapes (NSLP #5 or #6), and are generally regarded as transitional areas. The seasonal high water table can typically range from the soil surface to one foot below the surface for four to nine months annually. Examples of these soil series include Basinger, Malabar, and Riviera. Also included within this unit are occasionally flooded alluvial areas that have a sandy surface for the majority of the area. These areas may have a slightly shorter SHWT duration, but may be flooded for less than a few weeks by large

storm events. Please refer to Appendix C for a detailed description of the range of values for map units in this category.

Biological communities associated with this landscape position include cabbage palm flatwoods and hammocks, Everglades flatwoods, cutthroat seeps, wetland hardwood hammocks, scrub cypress, freshwater marsh, and wet-prairies. Local conditions favor one community over the other with fire frequency, soil thickness, and site hydrology playing large roles in controlling the dominant vegetation type. The fire dependant cutthroat grass (*Panicum abscissum*), an endemic, is restricted to seepage slopes and swales of south central Florida (Abrahamson and Hartnett, 1990). Dwarf (scrub) cypress forests are found on thin, rocky soils such as those along the southern peninsula. Generally, seldom burned sites tend to develop swamp forests, whereas frequently burned sites tend to support marsh or wet prairie vegetation. Please refer to Appendix D for a detailed description of Slough (wet prairie) ecological communities.

NSLP #8 Flatwood Soils

Flatwood soils are poorly drained nonhydric, upland soils with sandy marine sediments throughout the profile, some of which may have loamy sand substrates. Most of the soils in this category are Spodosols, (i.e., they have a subsurface spodic horizon). The seasonal high water table can range from one-half to one and one-half feet below the soil surface for four months annually. Examples of these soil series include Immokalee, Myakka, and Smyrna. Some areas may become inundated for less than a couple weeks during large storm events. Please refer to Appendix C for a detailed description of the range of values for map units in this category.

Biological communities associated with this landscape position include dry prairies, flatwoods (pine and cabbage palm), and low hammocks (i.e., hardwood, cabbage palm, and oak). Fire plays a key role in the development of one community type over another. Fire excluded sites tend to develop low hammocks, whereas frequently burned sites tend to develop flatwoods. Over-burned sites tend to become dry prairies, which are treeless (or nearly so) expanses dominated by grasses (e.g., *Aristida* spp., *Andropogon* spp.), saw palmetto (*Serenoa repens*), and low shrubs (e.g., wax myrtle, fetterbrush, gallberry, and shining blueberry) (Abrahamson and Hartnett, 1990). Please refer to Appendix D for a more detailed description of South Florida Flatwoods ecological community.

NSLP #9 Knolls

Knolls soils are nonhydric, moderately well to somewhat poorly drained upland soils with sandy marine sediments throughout the profile. These soils are Psamments (an Entisol), which typically have no unique diagnostic horizons throughout the soil profile. The seasonal high water table can range from one and one-half feet to six feet below the soil surface for four to seven months annually. Examples of these soils include Krome, Tavares, and Zolfo. Please refer to Appendix C for a detailed description of the range of values for map units in this category.

Biological communities associated with this landscape position include sand pine scrub, pine flatwoods, South Florida coastal strand, oak hammocks, tropical hammocks, and upland hammocks. Fire plays a key role in the development of one community over another. Fire-excluded sites develop hammocks, whereas frequently burned sites will support pine scrub or flatwoods. Tropical hammocks tend to be found along the coastal areas or along the extreme southern peninsula. Sand pine scrub (dominated by *Pinus clausa*), pine flatwoods (dominated by *Pinus elliottii*) and scrubby flatwoods (a community intermediate between the two) are fire-dependant forests that inhabit the dry soils of the coastal ridge and interior highlands north of Lake Okeechobee. Please refer to Appendix D for a more detailed description of the Sand Pine Scrub ecological community.

NSLP #10 Central Ridge & Dunes

Central Ridge & Dune landscapes are excessively drained, nonhydric, Psamments (an Entisol of drier upland soils) with sandy marine sediment throughout the profile. The seasonal high water table is more than six feet below the soil surface throughout the year. Common soils of this landscape position include Astatula, Candler, and Neilhurst. Please refer to Appendix C for a detailed description of the range of values for map units in this category.

Ecological communities that may be found on this landscape include sand pine scrub, scrubby flatwoods, South Florida coastal strand, and upland hardwood hammock. Fire plays an important role in the maintenance of sand pine scrub and scrubby flatwood habitats; these habitats will convert to hammock if burning is suppressed. Coastal strand is found primarily along the barrier islands of the Atlantic coast. Please refer to Appendix D for a more detailed description of the South Florida Coastal Strand ecological community.

NSLP #11 Urban or Made Lands

Urban or made land areas have been altered, excavated, or disturbed and no longer have their natural morphological soil features. These soils no longer function as they did in their original state, so there is little information available. The seasonal high water table varies by site and is usually controlled to inhibit flooding of developed areas. Common soils of this landscape position include Arents, Matlacha, Pits, Udorthents, and Urban Land.

NSLP #12 No Data

No data is available for these sites because of resource limitations or inaccessiblity. Some private land owners denied soil survey staff access to thier property. Public lands were not mappped unless the managing agency was willing to fund.

USE OF THE SOIL CLASSIFICATIONS

The classification schemes outlined in this document do not represent the only or best categorizations of the soils data. Our purpose is to present several classifications that are most needed by users of the soils data. The methods outlined in this technical publication do not improve the original county soil survey data quality, rather serves only to aid in its use. Other fields that may be categorized in the soils data base include: hydrological group, drainage class, depth to the bedrock, hydric soils, leaching potential, and runoff potential. It is then possible to generate a GIS map layer for that attribute. For example, a map of hydric soils or a map of soil drainage classes may be useful to hydrological modelers. It is recognized that different disciplines and different projects will have unique needs, and our purpose is to make the soils data more easily used by these groups.

Users of soil map data must also realize that even at the scales and levels of detail of the SSURGO maps, the map unit data are generalized to some degree. In reality, soils are highly variable across the landscape. Mapping efforts are limited by scale, time, monetary, and other limitations that can cause considerable imprecision in most soil maps (Brown et al., 1990). The landscape and soils are even more complex than depicted in the SSURGO maps.

Soil morphology reflects the complex interaction among topography, climate, time, vegetation, hydrology, and parent material. The morphological characteristics of soils are influenced by the hydrological conditions under which they formed, especially in South Florida where very small changes in topography can greatly affect hydrologic response. This fact is useful in interpreting map layers developed from the Soils Classification Database. Because soil morphology data yields information about the historic conditions of a site, it can be useful in interpreting the landscape before changes from development. By definition, hydric soils were formed in wetlands. The extent of hydric soils is also the historic extent of wetlands. This can have important implications for the management and restoration of wetlands, as well as in understanding the landscape in which they are situated. This can aid in understanding historical hydrological flow paths, runoff, and conditions, as well as predicting impacts to landscape-level features by encroaching development.

Some of our classifications generally define a hydrological gradient from lower, wetter landscapes (e.g., Water) to higher landscapes (Knolls, Central Ridge & Dunes). In undisturbed (e.g., nonurban, nonagricultural) areas, these classifications and the associated map layers are useful for understanding natural relationships between adjacent landscapes (relative topography), as well as regional patterns of hydrological and topographical gradients.

County soil surveys were conducted during different years and as a result, some contain more current data than others. In some coastal counties that have older surveys, the area of drained soils or urban lands are most likely under represented. Some soils that

are present in the database were converted to agriculture or urban areas after the soils survey was taken. Some large-scale hydrological alterations (e.g., canals and levees) may have permanently changed the natural drainage patterns of an area. When using data from counties that have older data, a more recent source of information should be sought for verification. **Table 4** shows the year that soil surveys were published.

Table 4. Dates of Publication of County Soil Surveys by NRCS.

County Soil Survey	Date(s) of Publication
Broward County (East)	1984
Charlotte County	1984
Collier County	1998
Miami-Dade County	1996
Glades County	1999
Hendry County	1990
Highlands County	1990
Indian River County	1987
Lee County	1984
Martin County	1981
Monroe County	1995
Okeechobee County (update)	1999
Orange County	1989
Osceola County	1979
Palm Beach County	1978
Polk County	1990
St. Lucie County	1980
Desoto County	1989
Hardee County	1984

As a result of substantial changes to local hydrology some peat soils are declining, necessitating a change in the classification of these soils (Collins et al., 1986; Griffin et al., 1982; Stephens et al., 1984; Snyder et al., 1978). It is recommended that organic soils within drained areas be verified before using data from the site.

Efforts will be made by the NRCS to keep this database updated, however its strength is in landscape-level application. It is recommended that when applying these data to a discrete location that a site-specific observation is used to confirm the map data. This data is intended to assist in analyzing the characteristics of soils, but can never replace site-specific observations when that level of resolution is required.

SUMMARY

The Soil Classification Database is a compilation and generalization of soil databases that is suitable for categorizing soils of similar characteristics. County soil surveys published by the Natural Resource Conservation Service (NRCS, formerly the Soil Conservation Service) are often difficult to use because of the format, size, and complexity of the data. The Soil Classification Database allows the soils data to be presented in a more user-friendly format.

The Soil Classification Database was derived from the Soil Survey Geographical Database (SSURGO) Component (COMP) table. The first (largest) soil components for each map unit and the most-used data fields were retained, then combined with several useful data fields from the Field Office Technical Guide (published by the Florida NRCS). Data were checked for accuracy and updated where necessary. The result was an updated single soils database that can be used to group soils into understandable categories of similar characteristics, such as the NSLP component.

The Soil Classification Database includes all counties within and several adjacent to the boundaries of the South Florida Water Management District (SFWMD) and is current to 1999 NRCS data standards and definitions. This project is a joint effort between the Comprehensive Conservation, Permitting, and Mitigation Strategy (Wetland Conservation Strategy) and the NRCS. Funding was provided as part of the USEPA's grant to the SFWMD for the Wetland Conservation Strategy.

GLOSSARY AND LIST OF ABBREVIATIONS

Component The individual soil types that make up a map unit.

Duration The length of time that the SHWT expresses itself. The duration of the SHWT is not a definite time span, rather it is a range typical for the map unit or category. This range is shorter in drier years and longer in unusually wet years. Also, the beginning and ending of the SHWT depends on the timing of rainfall events for the season. Usually the rainy season (which fuels the SHWT) begins in May. However, in some years the rainy season can begin in April or June, depending on climatic factors.

Ecological Community Categorization (ECC) A classification of the SSURGO data presented in this document.

Entisols A soil order that consists of poorly developed soils. In these soils, profile development is either minor or lacking altogether. Diagnostic characteristics found in other soil orders are not found, such as an organic, spodic, or argillic horizon. The most common Entisols found in South Florida are the Aquents (formed in wet environments) and the Psamments (found in naturally drier environments). Aquents are the dominant Entisols in South Florida, are found along the Rocky Glades area. Psamments are found along the Central Ridge and along the ancient dune line on the Coast.

Flooding The temporary covering of the soil surface by flowing water caused by overflowing streams, by runoff from adjacent slopes, or by inflow from high tides. Shallow water standing in swamps and marshes or in a closed depression is considered ponding. Frequency, duration, and probable dates are estimated. Frequency generally is expressed as *none* or f*requent. None* means that flooding is not probable. *Frequent* means that flooding occurs under normal weather conditions (more than a 50 percent chance of flooding in any year). Duration is expressed as *long* (7 days to 1 month), and *very long* (more than one month), The time of year that floods are most likely to occur is expressed in months. November-June, for example, means that flooding can ocur during the period November through June. About two-thirds to three-forths of all flooding occurs during the stated period.

FOTG Field Office Technical Guide.

GIS Geographic Information System.

Histosols A soil order that are predominantly organic, consisting of peat or muck deposits of varying thickness over sand, marl, limestone, or other material. The organic soil has accumulated in an extremely wet environment and can vary in consistency from fibrous to slimy (Davis, 1946; Brown et al., 1990). Different types of peat have been classified based on the parent plant material from which they are derived, the texture, composition, and state of decay (Davis, 1946; Cohen and Spackman, 1984). Peat deposits in South Florida are fairly recent, the oldest in the historic Everglades being approximately 5,000 years old (Gleason and Stone, 1994). It is important to note that when drained, peat is subject to subsidence, shrinking, and decomposition). Some estimated rates place this on the order of 2.5 cm/yr. In some areas where drainage has been effected, the extent of peat soils is declin-

ing, prompting a change in the classification of these soils (Collins et al., 1986; Griffin et al., 1982; Stephens et al., 1984; Snyder et al., 1978).

Map Unit The fundamental graphic feature in the SSURGO database which links the graphic feature to the attribute database. Each map unit represents an area dominated by one to three kinds of soil. However, there are no graphic deliniations for the locations of components within the map unit.

Hydric Soils Soils that are saturated, flooded, or ponded long enough during the growing season to develop anaerobic conditions in the upper part (USDA, Soil Conservation Service, 1987). This definition identifies soils that are either saturated or inundated long enough during the growing season to support the growth and reproduction of hydrophytic vegetation. The concept of hydric soil indicators is based on the theory that soils develop diagnostic morphological features associated with the anaerobic decomposition of organic matter and the reduction of iron and other minerals in their upper part. In other words, that when soils are wet enough for a long enough duration to be considered hydric, they should exhibit certain visible properties that are observable in the field. Wetlands possess three essential characteristics: (1) hydrophytic vegetation, (2) hydric soils, and (3) wetland hydrology. All manual criteria for each of the three characteristics must be met before an area can be identified as a wetland. Therefore, the synonymy of hydric soils and wetlands is implied (National Technical Committee for Hydric Soils, 1994).

MUID Map unit identification number.

NRCS Natural Resources Conservation Service (formally the Soil Conservation) A unit of the United States Department of Agriculture.

NSLP Natural Soils Landscape Positions, a classification of the SSURGO data presented in this document.

SCS Soil Conservation Service (see NRCS).

Seasonal High Water Table (SHWT) The shallowest depth to free water that stands in an unlined borehole or where the soil moisture tension is zero for a significant period (more than a few weeks). The depth to the SHWT is the most used/ requested soil interpretation in Florida. This method of estimating SHWT applies only to those areas lacking significant hydrological modifications. Hydrological modification such as ditches and dikes can make the soil either wetter or drier. The depth to the SHWT is not a definite value, rather it is a range typical for the map unit or category. This range may be larger

Spodosols A soil order that consists of soils that have a spodic horizon. The spodic, or Bh, horizon is a subsurface layer in which organic matter in combination with aluminum and/or iron has accumulated due to down-ward leaching. The upper boundary of this layer is within 2m of the soil surface and the soil textures are generally sandy. Two types of spodosols can be further defined, the Aquods (that are wet for extended periods in most years) and the Humods (that are not naturally wet for extended periods in most years).

Appendix A
SHWT CLASSIFICATION CODES

The classification codes for the SHWT ranges are shown in **Table A-1**. The values provided in SSURGO are the duration and range (high and low) for the SHWT in an average year. These values are for natural conditions at the time the county soil survey was undertaken. If drainage has been implemented, it is noted in the "other phase" or "OTHERPH" field in the Soils Classification Database. It is important to verify these data with currently available information before applying them since changes may have occurred since the soil survey was completed.

Table A-1. Category Codes and Associated Ranges for the SHWT Used in the Categorization of Duration.

Category Codes and Associated Ranges for the SHWT
100 Deep SHWT (from 2.5 to more than 6 ft. below the soil surface).
110 SHWT more than 6.0 ft below the soil surface.
119 SHWT more than 6.0 ft below the soil surface all year.
120 SHWT 5.0 to 6.0 ft below the soil surface.
121 SHWT 5.0 to 6.0 ft below the soil surface for 4 months annually.
122 SHWT 5.0 to 6.0 ft below the soil surface for 5 months annually.
129 SHWT 5.0 to 6.0 ft below the soil surface for 12 months annually.
130 SHWT 4.0 to 6.0 ft below the soil surface.
132 SHWT 4.0 to 6.0 ft below the soil surface for 5 months annually.
134 SHWT 4.0 to 6.0 ft below the soil surface for 7 months annually.
140 SHWT 4.0 to 5.0 ft. below the soil surface.
143 SHWT 4.0 to 5.0 ft. below the soil surface 6 months annually.
144 SHWT 4.0 to 5.0 ft. below the soil surface 7 months annually.
150 SHWT 3.5 to 6.0 ft. below the soil surface.
153 SHWT 3.5 to 6.0 ft. below the soil surface 6 months annually.
154 SHWT 3.5 to 6.0 ft. below the soil surface 7 months annually.
160 SHWT 3.5 to 5.0 ft. below the soil surface.
162 SHWT 3.5 to 5.0 ft. below the soil surface 5 months annually.
163 SHWT 3.5 to 5.0 ft. below the soil surface 6 months annually.
164 SHWT 3.5 to 5.0 ft. below the soil surface 7 months annually.
170 SHWT 3.0 to 5.0 ft. below the soil surface.
172 SHWT 3.0 to 5.0 ft. below the soil surface 5 months annually.
173 SHWT 3.0 to 5.0 ft. below the soil surface 6 months annually.
180 SHWT 2.5 to 5.0 ft. below the soil surface.
181 SHWT 2.5 to 5.0 ft. below the soil surface 4 months annually.
182 SHWT 2.5 to 5.0 ft. below the soil surface 5 months annually.
183 SHWT 2.5 to 5.0 ft. below the soil surface 6 months annually.
190 SHWT 2.0 to 8.0 ft. below the soil surface.
193 SHWT 2.0 to 8.0 ft. below the soil surface 6 months annually.
200 Beaches (Salt water table from 0.0 to 6.0 ft. below the soil surface).
210 Salt water table from 0.0 to 6.0 ft. below the soil surface.
219 Salt water table from 0.0 to 6.0 ft. below the soil surface all year.
300 SHWT varies widely (from 0 to 6 ft. below the soil surface).
310 SHWT 0.0 to 6.0 ft. below the soil surface.
312 SHWT 0.0 to 6.0 ft. below the soil surface 5 months annually.
314 SHWT 0.0 to 6.0 ft. below the soil surface 7 months annually.
400 SHWT well below the soil surface (from 1.0 to 4.0 ft. below the soil surface).
410 SHWT 2.5 to 3.5 ft. below the soil surface.

Table A-1. (Continued) Category Codes and Associated Ranges for the SHWT Used in the Categorization of Duration.

Category Codes and Associated Ranges for the SHWT
411 SHWT 2.5 to 3.5 ft. below the soil surface 4 months annually.
413 SHWT 2.5 to 3.5 ft. below the soil surface 6 months annually.
420 SHWT 2.0 to 4.0 ft. below the soil surface.
421 SHWT 2.0 to 4.0 ft. below the soil surface 4 months annually.
425 SHWT 2.0 to 4.0 ft. below the soil surface 8 months annually.
429 SHWT 2.0 to 4.0 ft. below the soil surface 12 months annually.
430 SHWT 2.0 to 3.5 ft. below the soil surface.
431 SHWT 2.0 to 3.5 ft. below the soil surface 4 months annually.
432 SHWT 2.0 to 3.5 ft. below the soil surface 5 months annually.
433 SHWT 2.0 to 3.5 ft. below the soil surface 6 months annually.
436 SHWT 2.0 to 3.5 ft. below the soil surface 9 months annually.
440 SHWT 2.0 to 3.0 ft. below the soil surface (includes 2.0 to 2.0).
441 2.0 to 3.0 ft. below the soil surface 4 months annually.
442 2.0 to 3.0 ft. below the soil surface 5 months annually.
443 2.0 to 3.0 ft. below the soil surface 6 months annually.
450 SHWT 1.5 to 3.5 ft. below the soil surface.
451 SHWT 1.5 to 3.5 ft. below the soil surface 4 months annually.
453 SHWT 1.5 to 3.5 ft. below the soil surface 6 months annually.
460 SHWT 1.5 to 3.0 ft. below the soil surface.
461 SHWT 1.5 to 3.0 ft. below the soil surface 4 months annually.
463 SHWT 1.5 to 3.0 ft. below the soil surface 6 months annually.
470 SHWT 1.5 to 2.5 ft. below the soil surface.
472 SHWT 1.5 to 2.5 ft. below the soil surface 5 months annually.
480 SHWT 1.0 to 3.5 ft. below the soil surface.
483 SHWT 1.0 to 3.5 ft. below the soil surface 6 months annually.
490 SHWT 1.0 to 3.0 ft. below the soil surface.
493 SHWT 1.0 to 3.0 ft. below the soil surface 6 months annually.
500 SHWT is shallow (from 0.5 to 1.5 ft. below the soil surface).
510 SHWT is 1.0 to 1.5 ft. below the soil surface.
511 SHWT is 1.0 to 1.5 ft. below the soil surface 4 months annually.
520 SHWT is 1.0 ft. below the soil surface.
529 SHWT is 1.0 ft. below the soil surface 12 months annually.
530 SHWT is 0.5 to 1.5 ft. below the soil surface.
530 SHWT is 0.5 to 1.5 ft. below the soil surface 3 months annually.
531 SHWT is 0.5 to 1.5 ft. below the soil surface 4 months annually.
532 SHWT is 0.5 to 1.5 ft. below the soil surface 5 months annually.
533 SHWT is 0.5 to 1.5 ft. below the soil surface 6 months annually.
536 SHWT is 0.5 to 1.5 ft. below the soil surface 9 months annually.

Table A-1. (Continued) Category Codes and Associated Ranges for the SHWT Used in the Categorization of Duration.

Category Codes and Associated Ranges for the SHWT
540 SHWT is 0.5 to 1.0 ft. below the soil surface.
543 SHWT is 0.5 to 1.0 ft. below the soil surface 6 months annually.
600 High range for the SHWT is at the soil surface.
610 SHWT is 0.0 to 2.0 ft. below the soil surface.
619 SHWT is 0.0 to 2.0 ft. below the soil surface 12 months annually.
620 SHWT is 0.0 to 1.0 ft. below the soil surface.
620 SHWT is 0.0 to 1.0 ft. below the soil surface 3 months annually.
621 SHWT is 0.0 to 1.0 ft. below the soil surface 4 months annually.
622 SHWT is 0.0 to 1.0 ft. below the soil surface 5 months annually.
623 SHWT is 0.0 to 1.0 ft. below the soil surface 6 months annually.
624 SHWT is 0.0 to 1.0 ft. below the soil surface 7 months annually.
626 SHWT is 0.0 to 1.0 ft. below the soil surface 9 months annually.
629 SHWT is 0.0 to 1.0 ft. below the soil surface 12 months annually.
630 SHWT is 0.0 to 0.5 ft. below the soil surface.
631 SHWT is 0.0 to 0.5 ft. below the soil surface 4 months annually.
632 SHWT is 0.0 to 0.5 ft. below the soil surface 5 months annually.
633 SHWT is 0.0 to 0.5 ft. below the soil surface 6 months annually.
634 SHWT is 0.0 to 0.5 ft. below the soil surface 7 months annually.
638 SHWT is 0.0 to 0.5 ft. below the soil surface 11 months annually.
639 SHWT is 0.0 to 0.5 ft. below the soil surface 12 months annually.
640 SHWT is at the soil surface.
647 SHWT is at the soil surface 10 months annually.
700 High range for the SHWT is above soil surface.
710 SHWT is from 1 ft. above to 1 ft. below the soil surface.
711 SHWT is from 1 ft. above to 1 ft. below the soil surface 4 months annually.
712 SHWT is from 1 ft. above to 1 ft. below the soil surface 5 months annually.
713 SHWT is from 1 ft. above to 1 ft. below the soil surface 6 months annually.
714 SHWT is from 1 ft. above to 1 ft. below the soil surface 7 months annually.
716 SHWT is from 1 ft. above to 1 ft. below the soil surface 9 months annually.
719 SHWT is from 1 ft. above to 1 ft. below the soil surface 12 months annually.
720 SHWT is from the soil surface to 1 ft. above the surface.
722 SHWT is from the soil surface to 1 ft. above the surface 5 months annually.
725 SHWT is from the soil surface to 1 ft. above the surface 8 months annually.
726 SHWT is from the soil surface to 1 ft. above the surface 9 months annually.
728 SHWT is from the soil surface to 1 ft. above the surface 11 months annually.
730 SHWT is from 2 ft. above to 1ft. below the soil surface.
731 SHWT is from 2 ft. above to 1ft. below the soil surface 4 months annually.
732 SHWT is from 2 ft. above to 1ft. below the soil surface 5 months annually.

Table A-1. (Continued) Category Codes and Associated Ranges for the SHWT Used in the Categorization of Duration.

Category Codes and Associated Ranges for the SHWT
734 SHWT is from 2 ft. above to 1ft. below the soil surface 7 months annually.
736 SHWT is from 2 ft. above to 1ft. below the soil surface 9 months annually.
737 SHWT is from 2 ft. above to 1ft. below the soil surface 10 months annually.
740 SHWT is from the soil surface to 2 ft. above the surface.
741 SHWT is from the soil surface to 2 ft. above the surface 4 months annually.
742 SHWT is from the soil surface to 2 ft. above the surface 5 months annually.
744 SHWT is from the soil surface to 2 ft. above the surface 7 months annually.
745 SHWT is from the soil surface to 2 ft. above the surface 8 months annually.
746 SHWT is from the soil surface to 2 ft. above the surface 9 months annually.
747 SHWT is from the soil surface to 2 ft. above the surface 10 months annually.
748 SHWT is from the soil surface to 2 ft. above the surface 11 months annually.
749 SHWT is from the soil surface to 2 ft. above the surface 12 months annually.
800 Water areas. Water table is 2 ft. or more above the soil surface 12 months annually.
900 No data available for this area.

Appendix B
ECOLOGICAL COMMUNITY CATEGORY DEFINITIONS

Table B-1. Category Definitions for the Ecological Community Categories.

Category Number	Category Name	Primary Ecological Communities (as defined by NRCS, 1989)	Category Definition and Description
1	Water	None	Permanently inundated areas. "Water" map units selected from database.
2	Intra-Tidal Wetlands	Salt Marsh (#18) Mangrove Swamp (#19)	Low wave energy coastal wetlands. Ecological communities #18 and #19 selected from database.
3	Beaches	None	High wave energy coastal lands that support beach communities. "Beaches" map units selected from database.
4	Freshwater Wetlands	Scrub Cypress (#16) Cypress Swamp (#17) Swamp Hardwoods (#21) Sawgrass Marsh (#24) Freshwater Marsh (#25)	Freshwater marshes and ponds. Ecological communities #9 (if SHWT-CAT 1 = 700), #12 (if SHWT-CAT 1 = 700), #16, #17, #21, #22 (if SHWT-CAT 1 = 700), #24 (if SHWT-CAT 1 = 700), #25, and #26 (if SHWT-CAT 1 = 700) selected from database.
5	Swamp Hammock	Wetland Hardwood Hammocks (#12) Shrub Bogs - Bay Swamps (#22)	Transitional mesic forested communities. Ecological communities #11 (if SHWT-CAT 1 = 600), #12 (if SHWT-CAT 1 < 700), #13 (if SHWT-CAT 1 = 600 and hydric soil), #14 (SHWT-CAT 1 = 600), and #22 (if SHWT-CAT 1 = 600) selected from database.
6	Wet Prairie	Cutthroat Seeps (#10) Slough (#26)	Freshwater wet prairies. Ecological communities. Ecological communities #8 (SHWT-CAT 1 = 600), #10, #24 (SHWT-CAT 1 = 600), and #26 (SHWT-CAT 1 = 600) selected from database.
7	Flatwoods	South Florida Flatwoods (#6) Everglades Flatwoods (#9)	Pine or palm dominated flatwood communities. Ecological communities #6 (if SHWT-CAT 1 > 500), #8 (if SHWT-CAT 1 = 500), #9 (if SHWT-CAT 1 = 500 or 600), #13 (if SHWT-CAT 1 = 600 and nonhydric soil) selected from database.
8	Uplands	Upland Hardwood Hammocks (#11) Tropical Hammocks (#14)	Upland forested communities that seldom flood. Ecological communities #3 (if SHWT-CAT 1 = 400), #4 (if SHWT-CAT 1 > 300), #6 (if SHWT-CAT 1 = 400), #11 (if SHWT-CAT 1 = 400), #13 (if SHWT-CAT 1 = 500), #14 (if SHWT-CAT 1 = 400 or 500), #15, and #24 (if SHWT-CAT 1 = 400) selected from database.
9	Highlands	North Florida Coastal Strand (#1) South Florida Coastal Strand (#2) Sand Scrub (#3) Longleaf Pine - Turkey Oak Hills (#4)	Scrub or xeric communities. Flooding never occurs. Ecological communities #1, #2 (except beaches), #3 (if SHWT-CAT 1 < 400), #4 (if SHWT-CAT 1 < 300), #6 (if SHWT-CAT 1 = 100), #9 (if SHWT-CAT 1 = 100), #11 (if SHWT-CAT 1 = 100), and #14 (if SHWT-CAT 1 = 100) selected from database.
10	N/A	No data available for these map units.	Selected "No Data" ecological community entries, urbanized, and drained map units.

Appendix D
SELECTED ECOLOGICAL COMMUNITIES

The following descriptions of ecological communities are based on the NRCS publication *The 26 Ecological Communities of Florida* (SCS, 1989).

SOUTH FLORIDA COASTAL STRAND (ECOLOGICAL COMMUNITY NO. 2)

Range: The South Florida Coastal Strand ecological community occurs along the Atlantic Ocean south of Brevard County and along the Gulf of Mexico south of Pasco County. Individual communities are generally large in size, being narrow, long, and parallel to the coastal beaches. Small, isolated communities can also be found along some bays or sounds. This community generally encompasses the area affected by salt sprays from the ocean, gulf, and saltwater bays.

Soils: The soils are nearly level to strongly sloping, deep, mostly well to excessively drained with some moderately well drained or somewhat poorly drained. They are coarsely textured throughout. Representative soils include: Canaveral and Palm Beach. It also includes areas mapped as Coastal Beach and Coastal Beach Ridges.

Vegetation: The natural vegetation of this community is low growing grasses, vines, and herbaceous plants with few trees or large shrubs. These trees and shrubs often occur in stunted form due to the action of the wind. The natural forces of wind, salt, and blowing sand make plant establishment difficult on the foredunes. Plants which do establish here are well adapted to disturbance and are pioneer species. The backdunes will often have vegetation similar to the sand pine scrub or the wetland hardwood hammock ecological communities. Plants which characterize this community are: cabbage palm (*Sabal palmetto*), coconut palm (*Cocos nucifera*), sand live oak (*Quercus virginiana* var. *maritima*), bay cedar (*Suriana maritima*), inkberry (*Scaevola plumieri*), marsh elder (*Iva imbricata*), saw palmetto (*Serenoa repens*), silverleaf croton (*Croton punctatus*), Spanish bayonet (*Yucca aloeifolia*), sea grape (*Coccoloba uvifera*), bay bean (*Canavalia maritima*), railroad vine (*Ipomoea pes-caprae*), beachdune sunflower (*Helianthus debilis*), sea purslane (*Sesuvium portulacastrum*), sea oats (*Uniola paniculata*), seashore paspalum (*Paspalum vaginatum*), and seashore saltgrass (*Distichlis spicata*). The following endangered or threatened plants may occur in this community: beach star (*Remirea maritima*), small flowered lily-thorn (*Catesbaea parviflora*, Florida Keys), burrowing four-O'clock (*Okenia hypogaea*), sea lavender (*Mallatonia gnaphalodes*), beach creeper (*Ernodea littoralis*), west coast prickly apple (*Cereus gracilis*), and the fragrant prickly apple (*Cereus eriophorus* var. *frangrans*), St. Lucie County.

Wildlife: A variety of shorebirds, terns, and gulls can be found on or near the beach. This community provides good food sources as well as nesting sites. Small mammals can also be found on the coastal dunes. Larger mammals also occur behind the

foredunes. Some species that occur are: bobcat (*Lynx rufus*), eastern spotted skunk (*Spilogale putorius*), raccoons (*Procyon lotor*), mice, American kestrel (*Falco sparverius*), pelicans, gulls, terns, shorebirds, songbirds, frogs, and lizards. This area also serves as nesting grounds for sea turtles. Crustaceans such as crabs are numerous near the shorelines. The following protected species may be found in or around this community: pallid beach mouse (*Peromyscus polionotus decoloratus*), Goff's pocket gopher (*Geomys pinetis goffi*), peregrine falcon (*Falco peregrinus tundrius*), piping plover (*Charadrius melodus*), southeastern snowy plover (*Charadrius alexandrinus tenuirostris florida*), least tern (*Sterna antillarum*), Atlantic green turtle (*Chelonia mydas mydas*), Atlantic coast only), Atlantic hawksbill turtle (*Eretmochelys imbricata imbricata*), Atlantic loggerhead turtle (*Caretta caretta caretta*), Atlantic ridley turtle (*Lepidochelys kempi*), and the leatherback turtle (*Dermochelys coriacea*).

Environmental Value as a Natural System: The coastal strand is highly endangered. Areas privately owned but undeveloped are in demand for residences, hotels and motels. This urban development can have serious effects on the community. Coastal strands are important in regulating wave action along the coast. This action tends to break away part of one beach and build up another. Unplanned structures and development which alter this process accelerates beach and coastal dune erosion through removal of native vegetation, which helps hold the dune together, and by removal of sand from the offshore transport system. Recreational use and wildlife values on the coastal strand are important. Recreation is much in demand in these areas but can cause damage due to trampling and destroying vegetation. When these plants die, their extensive root systems are no longer available to hold the soil together and build the dune. Occasional use may also degrade this fragile community.

Rangeland: This community is not generally used for rangeland.

Woodland: This community is not generally used for woodland.

Urbanland: The better drained areas inland from the ocean or gulf have few limitations for urban development. Areas adjacent to the water may be subject to coastal dune and beach erosion. This is especially true where construction alters the natural processes and destroys excessive amounts of native vegetation. Vegetation is difficult to establish because of the infertile, coarse textured, well to excessively well drained and saline soils and the salt spray. Intensive vegetation establishment and maintenance methods are needed for best results. Without vegetation, water and wind erosion can become a problem during and after construction. Plants native to the community should receive preference for beautification and landscaping. This is because they are more easily established and require less maintenance. Some of the trees are: cabbage palm, coco plum (Chrysobalanus icaco), Florida thatch palm (*Thrinax* spp.), Florida silver thatch palm (*Coccothrinax argentata*), live oak (*Quercus virginiana*), pigeon plum (*Coccoloba diversifolia*), red bay (*Persea borbonia*), slash pine (*Pinus elliottii* var. *densa*), magnolia (*Magnolia grandiflora*), wild tamarind (*Lysiloma latisiliqua*), and sand pine (*Pinus clausa*). Some of the shrubs are: prickly pear cactus (*Opuntia* spp.), sea grape (*Coccoloba uvifera*), coontie (*Zamia pumila*), coral bean (*Erythrina herbaceae*), yaupon holly (*Ilex:vomitoria*), lantanas, partridge pea (*Cassia* spp.), marsh elder (*Iva* spp.) saw

palmetto, Spanish bayonet, and wax myrtle (*Myrica cerifera*). Some of the grasses and herbaceous plants include: sea oats (*Uniola paniculata*), marsh hay cordgrass (*Spartina patens*), seashore dropseed (*Sporobolus virginicus*), blanket flower (*Gaillardia pulchella*), sea purslane (*Sesuvium portulacastrum*), and wild grape (*Vitis rotundifolia*).

SAND PINE SCRUB (ECOLOGICAL COMMUNITY NO. 3)

Range: The Sand Scrub ecological community occurs throughout Florida. It is most commonly found inland from the coast and in the central portion of the state in and around Marion County. Individual communities are generally small in size, (several hundred acres) and a few remnants still exist along the southeast coast in Palm Beach and Martin counties. A large community (several thousands of acres in size) occurs just east of Ocala in the Ocala National Forest. It typically has a few smaller communities of wetland types interspersed throughout.

Soils: The soils are nearly level to strongly sloping, deep, acid, somewhat poorly to excessively drained and course textured throughout. Representative soils include Archbold and Pomello.

Vegetation: The natural vegetation of this community may be typically even-aged sand pine trees with a dense understory of oaks, saw palmetto (*Serenoa repens*), and other shrubs. Ground cover under the trees and shrubs is scattered and large areas of light colored sand are often noticeable. In other cases, the sand pine are scattered or absent, with oaks being the dominant vegetation. Satellite soils, which have a high water table for part of the year, support scrubby growth also, but the myrtle oak, Chapman oak, and sand pine become infrequent and gallberry (*Ilex glabra*) becomes prominent. Plants which characterize this community are: Chapman oak (*Quercus chapmannii*), myrtle oak (*Quercus mytifolia*), sand live oak (*Quercus virginiana* var. *geminata*), sand pine (*Pinus clausa*), gopher apple (*Chrysobalanus oblongifolius*), prickly pear (*Opuntia* spp.), saw palmetto, grassleaf goldenaster (*Heterotheca graminifolia*), deermoss (*Cladonia spp.*), cat greenbriar (*Smilax glauca*), yellow Indian grass (*Sorghastrum nutans*), and low panicum (*Panicum* spp.). The following protected plants may occur in this community: four-petal pawpaw (*Asimina tetramera*), pigmy fringetree (*Chionanthus pyfmaea*), Curtis' milkweed (*Asclepias curtissii*), dancing-lady orchid, (*Tolumnia bahamense*), and Florida bonamia (*Bonamia grandiflora*).

Wildlife: Animals found in this community are adapted to high temperatures and droughty conditions. The wildlife food production is low. Dense vegetation provides good escape cover for animals such as deer (*Odocoileus virginianus*). The palmetto, various species of oaks and gopher apple provide good food sources. Typical animals of the sand scrub are: towhee (*Popilo erythrophthalmus*), great crested flycatcher (*Myiarchus crinitus*), Bachman's sparrow (*Aimophila aestivalis*), black racer (*Coluber constrictor*), gopher tortoise (*Gopherus polyphemus*), scrub lizard (*Sceloporus woodi*), and the gopher frog (*Rana areolata*). The following protected wildlife species may be found in or around this community: Goff's pocket gopher (*Geomys pinetis goffi*), Florida scrub jay (*Aphelocoma coerulescens coerulescens*), blue-tailed mole skink (*Eumeces egregius*

lividus), sand skink (*Neoseps reynoldsi*), and the short-tailed snake (*Stilosoma extenuatum*).

Environmental Value as a Natural System: The sand scrub is a fire-based community. Understory vegetation is dense and fuel supplies build up in the trees. The thick understory creates a pathway for fire to the crowns of the trees. Fire normally occurs every 20 to 40 years. Sand pines have a low resistance to fire and the high density, even-aged stands make fire devastating to this community. Cones of the sand pine require the heat of a fire to open and release seeds. This method of regeneration helps to form even-aged stands. Without occasional fire, this community would tend to become a type of upland hammock community. The sand scrub is a valuable ecological community. The coarse textured, excessively well drained soils make the community important in aquifer recharge. It is a unique ecosystem which gives it an important scientific value. Heat and drought stress response by plants and animals are often studied on these sites. Uncontrolled fire and damage to vegetation by excessive foot or vehicle travel have adverse effects on the community.

Rangeland: This community supports a fairly dense stand of trees and shrubs and therefore has a limited potential for producing native forage. Livestock do not use this site if other ecological communities are available. For sites in excellent condition the average annual production of air dry plant material varies from 1,500 to 3,500 pounds per acre. The variation depends on plant growth conditions. From fifteen to more than forty acres are usually needed per animal unit depending upon amount and type of forage available. The relative percentage of annual vegetative production by weight is 40 percent grasses, 40 percent trees and shrubs and 20 percent herbaceous plants and vines. Adverse soils conditions make it infeasible to convert this community to cropland. It has been converted to some extent for citrus production in South Florida.

Woodland: Sand scrubs are good producers of sand pine and some areas are utilized for commercial wood production. Intensive management for wood production will not cause excessive damage to the community if good silvicultural practices are applied. There are severe equipment limitations and moderate seedling mortality problems due to loose, well to excessively well-drained and infertile soil conditions. Sand pine is a commercial species suitable for planting. It has a potential annual growth of approximately 0.5 cords per acre in North Florida. South of Hernando County in the west and Orange County in the east, the potential annual growth is 0.4 cords per acre.

Urbanland: The moderately well to excessively well drained areas have few limitations for urban development. The somewhat poorly drained Satellite soils, although very droughty in the surface layers, have a water table at 20 inches for part of the year and has more limitations. Vegetation is difficult to establish because of the infertile, coarse textured, and droughty surface soils. Water moves rapidly through the soil. Intensive vegetation establishment and maintenance methods, including irrigation are needed for best results. Without vegetation, wind erosion can be a problem during and after construction. Water erosion control and water retention facilities are usually not needed. Plants native to the community should receive preference for beautification and landscaping. This is because they are more easily established and require less

maintenance. Some of the trees are: live oak, sand live oak, sand pine, turkey oak (*Quercus laevis*), and red cedar (*Juniperus silicicola*). Some of the shrubs are: Spanish bayonet (*Yucca aloeifolia*), coral bean (*Erythrina herbaceae*), gopher apple, pawpaw (*Asimina* spp.), prickly pear cactus (*Opuntia* spp.), rosemary (*Ceratiola ericoides*), saw palmetto, and shining sumac (*Rhus copallinum*). Some of the herbaceous plants are: asters, blanketflower (*Gaillardia pulchella*), blazing star (*Liatris* spp.), golden aster (*Pityopsis graminifolia*), goldenrods (*Solidago* spp.), lupine (*Lupinus* spp.), morning glories (*Ipomoea* spp.), and beach dune sunflower (*Helianthus debilis*).

SOUTH FLORIDA FLATWOODS (ECOLOGICAL COMMUNITY NO. 6)

Range: The South Florida Flatwoods ecological community occurs throughout South and Central Florida. The northern limit of its occurrence is approximately on a line from Levy County on the west to St. Johns County on the east. This community covers more land area than any other in South Florida. Individual communities may comprise several thousand acres and are typically interspersed with smaller communities of other types, especially wetlands. This community occurs on nearly level land. Water movement is very gradual to the natural drainageways, swamps, marshes, and ponds associated with this community. During the rainy season, usually June through September, this community may have water on or near the soil surface. It is easily identified by the flat topography and pine and palmetto vegetation.

Soils: The soils are nearly level, deep, acid, poorly to somewhat poorly drained. They are usually course textured in the upper part and variably textured below. Representative soils include: Electra, Immokalee, and Myakka.

Vegetation: The landscape position of this community affects plant-water relationships and causes slight differences in plant composition from wetter to drier areas. Although these differences are recognized, they are not significant enough to delineate as separate communities. The natural vegetation of this community is typically scattered pine trees with an understory of saw palmetto (*Serenoa repens*) and grasses. Some of these areas in South Florida have few, if any, trees. These are often called prairies or dry prairies. The largest of these areas occur north and west of Lake Okeechobee. Plants which characterize this community are: live oak (*Quercus virginiana*), South Florida slash pine (*Pinus elliottii var. densa*), ground blueberry (*Vaccinium myrsinites*), gallberry (*Ilex glabra*), tarflower (*Befaria racemosa*), shining sumac (*Rhus copallinum*), wax myrtle (*Myrica cerifera*), chalky bluestem (*Andropogon capillipes*), South Florida bluestem (*Schizachyrium rhizomatum*), and the pineland threeawn (*Aristida stricta*).

Wildlife: The South Florida Flatwoods community is host to a diverse and numerous wildlife population. Many larger animals are found in areas where the flatwoods join other communities. These ecotones provide nesting sites, den sites, food and cover. Typical animals of the flatwoods are: armadillo (*Dasypus novemcinctus*), rabbits, cotton rat (*Sigmodon hispidus*), deer (*Odocoileus virginianus*), eastern spotted skunk (*Spilogale putorius*), raccoons (*Procyon lotor*), opossum (*Didelphis virginiana*),

Bachman's sparrow (*Aimophila aestivalis*), bobwhite quail (*Colinus virginianus*), brown-headed nuthatch (*Sitta pusilla*), eastern meadowlark (*Sturnella magna*), pileated woodpecker (*Dryocopus pileatus*), pine warblers (*Dendroica pinus*), rufous-sided towhee (*Pipilo erythrophthalmus*), eastern diamondback rattlesnake (*Crotalus adamanteus*), oak toad (*Bufo quercicus*), and the pinewoods tree frog (*Hyla femoralis*). Introduced feral hogs are common in much of the community. The following endangered or threatened wildlife species may be found in or around this community: Florida panther (*Felis concolor coryi*), mangrove fox squirrel (*Sciurus niger avicennia*), crested caracara, Florida grasshopper sparrow (*Ammodramus savannarum floridanus*), southeastern kestrel (*Falco sparverius paulus*), red-cockaded woodpecker (*Picoides borealis*), bald eagle (*Haliaeetus leucocephalus*), sandhill crane (*Grus canadensis pratensis*), and the eastern indigo snake (*Drymarchon corais couperi*).

Environmental Value as a Natural System: Fire and water are the major stress conditions of this community. Fire controls hardwoods and promotes the natural regeneration of pine. Removal of fire will cause a successional move to a hardwood community. Flatwood communities are good cellulose producers and the original areas of predominantly longleaf pine have been logged. Areas in the northern part of the community are extensively used for timber production. Intensive management for pulp production can cause major changes in the vegetation. Without proper consideration this results in a low diversity of plants and an adverse change in some wildlife populations. This community has good wildlife values, especially with proper management. It is especially important as a wildlife buffer zone between urban areas occurring on better drained sites.

Rangeland: This ecological community has the potential for producing significant amounts of high quality native forage such as chalky bluestem, and indian grass (*Sorghastrum* spp.). It is Florida's most important community for the production of cattle on native range. For sites in excellent condition, the average annual production of air dry plant material varies from 3,000 to 6,000 pounds per acre. The variation depends on plant growth conditions. From four to more than eighteen acres are usually needed per animal unit depending upon amount and type of forage available. There will be little forage available if the canopy cover exceeds 60 percent. The relative percentages of annual vegetative production by weight is 75 percent grasses and grass-like plants, 15 percent trees and shrubs, and 10 percent herbaceous plants.

Woodland: This community has a moderate potential productivity for commercial wood production. There are moderate equipment limitations and seedling mortality due to wet soil conditions. The commercial species suitable for planting is slash pine. Potential annual growth is 0.9 cords per acre. The potential annual growth for longleaf pine is 0.5 cords per acre. Potential productivity is 18 percent less for soils south of a line from Hernando County in the west to Orange County in the east.

Urbanland: This community is subject to high water tables during the rainy season and has limitations for urban development. Water management systems are required for urban uses. It is often difficult to establish vegetation on steep channel side slopes and infertile soil and special techniques may be required. Without vegetation,

erosion and sedimentation is often a problem in some water management systems. Wind erosion is a problem in unvegetated areas. This is especially severe in the spring. Native plants can be used for beautification and require minimum establishment and maintenance. Some of the trees are: cabbage palm (*Sabal palmetto*), persimmon (*Diospiros virginiana*), live oak (*Quercus virginiana*), and slash pine (*Pinus elliottii* var. *densa*). Some of the shrubs are: American beauty berry (*Callicarpa americana*), coontie (*Zamia pumila*), coral bean (*Erythrina herbaceae*), partridge pea (*Cassia* spp.), pawpaw (*Asimina reticulata*), saw palmetto (*Serenoa repens*), shining sumac (*Rhus copallinum*), tarflower (*Befaria racemosa*), and wax myrtle (*Myrica cerifera*). Some of the herbaceous plants are: blazing star (*Liatris* spp.), pineland lily (*Lilium catesbaei*), asters, meadow beauty (*Rhexia* spp.), and zephyr lily (*Zephyranthes* spp.).

SCRUB CYPRESS (ECOLOGICAL COMMUNITY NO. 16)

Range: The Scrub Cypress ecological community occurs only in South Florida on marl and rock that is frequently flooded. Eastern Collier County and northern Monroe County have the largest areas of this community. This region is called "Big Cypress." This community appears as a broad area of marshes with dwarf cypress (less than 20 feet tall) scattered throughout. It is stressed by the extreme seasonal change in water levels, and low level of plant nutrients. These factors cause poor growing conditions with a lack of plant diversity and small wildlife populations in comparison to the cypress swamp community.

Soils: The soils associated with this community are nearly level, poorly to very poorly drained, with coarse to medium textured surfaces underlain by finer textured material or fractured limestone. A representative soil is Margate.

Vegetation: The vegetation is much like that of the freshwater marsh community. Occasional air plants and orchids can be found in the scattered cypress trees. Plants which characterize this community are: bald cypress (*Taxodium distichum*), pond cypress (*Taxodium distichum* var. *nutans*), wax myrtle (*Myrica cerifera*), stiff-leafed wild pine (*Tillandsia fasiculata*), yellow-eyed grass (*Xyris* spp.), blue maidencane (*Amphicarpum muhlenbergianum*), bluejoint panicum (*Panicum tenerum*), chalky bluestem (*Andropogon capillipes*), cutgrass (*Leersia hexandra*), gulfdune paspalum (*Paspalum monostachyum*), and maidencane (*Panicum hemitomon*). The following protected plant species may be found in or around this community: Acuna's epidendrum (*Epidendrum acunae*), auricled spleenwort (*Asplenium auritum*), bird's nest spleenwort (*Asplenium serratum*), cow-horn orchid (*Cyrtopodium punctatum*), dwarf epidendrum (*Encyclia pygmaea*), hidden orchid (*Maxillaria crassifolia*), leafless orchid (*Campylocentrum pachyrrhizum*), night-scented orchid (*Epidendrum nocturnum*), and nodding catopsis (*Catopsis nutans*).

Wildlife: The poor soil and lack of plant nutrients that are responsible for the relatively sparse plant life also account for a fairly scattered wildlife population. This community is one of the least productive of wildlife. Deer (*Odocoileus virginianus*) will range through these areas, but the habitat is poor. The primary value is seasonal to frogs, turtles, snakes, and salamanders which can adjust to the short hydroperiod. It is also use

by predators of these animals such as raccoons (*Procyon lotor*), mink (*Mustela vison*), and wading birds. Other wildlife species include bobcat (*Lynx rufus*), and herons. The following protected animal species may be found in or around this community: Florida panther (*Felis concolor coryi*), roseate spoonbill (*Ajaja ajaja*), wood stork (*Mycteria americana*), and American alligator (*Alligator mississippiensis*).

Environmental Value as a Natural System: The scrub cypress community occurs primarily in southwest Florida. Developments in and around the community cause changes in water quality and quantity which results in wide changes in portions of the plant community. The scrub cypress community is highly endangered. Scrub cypress swamps provide water storage areas by holding excess water and slowly releasing it into the water table. Water quality is enhanced by the community, which functions like a waste treatment plant by absorbing nutrients from the water.

Rangeland: This ecological community has the potential for producing significant amounts of high quality forage such as South Florida bluestem, gulfdune paspalum, chalky bluestem, and bluejoint panicum. For sites in excellent condition, the average annual production of air dry plant material varies from 1,500 to 4,500 pounds per acre. The variation depends on plant growth conditions. From nine to more than twenty-two acres are usually needed per animal unit depending upon amount and type of forage available. The relative percentages of annual vegetative production by weight is 75 percent grasses and grass-like plants, 15 percent trees and shrubs, and 10 percent herbaceous plants.

Woodland: These areas are not generally used for commercial woodland production. However, this community does have a moderate potential productivity for commercial woodland production on areas with adequate surface drainage. There are severe equipment limitations due to the poorly drained soil conditions. Slash pine is the species suitable for planting on areas with adequate surface drainage. Potential annual growth is 0.7 cords per acre.

Urbanland: This community is subject to periodic flooding and has severe limitations for urban development. Elaborate water management systems are required for urban uses. It is difficult to establish vegetation on steep channel side slopes and infertile spoil. Special techniques such as mulching, selected plants, and unusual seeding and plant management techniques may be required. Native plants can be used for beautification and require minimum establishment and maintenance. Some of the trees are: bald cypress, cabbage palm (*Sabal palmetto*), pond cypress, and slash pine (*Pinus elliottii* var. *densa*). Some of the shrubs are buttonbush (*Cephalanthus occidentalis*), dahoon holly (*Ilex cassine*), and wax myrtle.

CYPRESS SWAMP (ECOLOGICAL COMMUNITY NO. 17)

Range: The Cypress Swamp ecological community occurs along rivers, lake margins, slough and strands, or interspersed throughout other communities such as Flats (NSLP #7) and Flatwoods (NSLP#8). It occurs throughout Florida, but is the predominant

swamp type in the area from Flagler County south through Polk County, and in southwest Florida. The "Big Cypress" area of Monroe and Collier counties is included in ecological community #16- Scrub Cypress.

Soils: This community is poorly drained and water is at or above ground level a good portion of the year. Soils commonly associated with this community are nearly level or depressional, poorly drained and have loamy subsoils and sandy surfaces.

Vegetation: Bald cypress (*Taxodium distichum*) is the dominant tree and is often the only plant which occurs in significant numbers. The diversity of tree species is low in cypress heads but increases in strands and along stream margins. The submergence or saturated condition of the soil and general absence of fire help reduce competition and keeps the community from a successional change to a swamp hardwood (bay head) community. Cypress swamps growing on sand, rock, and shallow mucky pond areas are not as productive as those found on alluvial flood plain soils. Plants which characterize this community are: bald cypress, pond cypress (*Taxodium distichum* var. *nutans*), coastal plain willow (*Salix caroliniana*), red maple (*Acer rubrum*), buttonbush (*Cephalanthus occidentalis*), wax myrtle (*Myrica cerifera*), cinnamon fern (*Osmunda cinnamomea*), royal fern (*Osmunda regalis*), Spanish moss (*Tillandsia usneoides*), giant wild pine (*Tillandsia utriculata*), and maidencane (*Panicum hemitomon*). Some of the protected plants that may be found in this ecological community include: the bird's nest spleenwort (*Asplenium serratum*), climbing dayflower (*Commelina gigas*), fuzzy-wuzzy airplant (*Tillandsia pruinosa*), giant water dropwort (*Oxypolis greenmanii*), hidden orchid (*Maxillaria crassifolia*), nodding catopsis (*Catopsis nutans*), and grass-of-Parnassus (*Parnassia graniflora*).

Wildlife: This community is very important as a wildlife refuge and roosting area. It is well-suited for waterfowl and wading birds. Aquatic animals may be found in large numbers. The permanent residents of cypress heads are relatively few, but much of the wildlife of the flatwoods is dependent on these ponds for breeding purposes. The most common wildlife species include: deer (*Odocoileus virginianus*), raccoons (*Procyon lotor*), river otters (*Lutra canadensis*), Anhinga (*Anhinga anhinga*), barred owl (*Strix varia*), egrets, herons, limpkins (*Aramus guarauna*), pileated woodpecker (*Drycopus pileatus*), wood ducks (*Aix sponsa*), frogs, turtles, and a variety of water snakes. Some protected animal species that may be found in this ecological community include: Everglades mink (*Mustela vison evergladensis*), wood stork (*Mycteria americana*), American alligator (*Alligator mississippiensis*), bald eagle (*Haliaeetus leucocephalus*), and the Florida black bear (*Ursus americanus floridanus*).

Environmental Value as a Natural System: Cypress swamps are an extremely valuable resource. They can be used for environmental education study, scientific research, and recreation. They have a high value for use as wildlife habitat. This community has a relatively low diversity of plant species due to fluctuating water levels and low nutrient availability. Both drastic changes in mean water level and a stabilized water level may change the plant community. Often this will occur due to the effects of dams, dikes, or drainage channels. Stagnant water will result in slow tree growth especially if it occurs during the growing season. Natural regeneration of cypress requires

fluctuation of the water and flooding during the dry season will prevent the cypress trees from reproduction.

Rangeland: This community has little or no value as rangeland.

Woodland: Extensive drainage would be required, thereby destroying this community.

Urbanland: This community is subject to periodic flooding and has severe limitations for urban development. Elaborate water management systems are required for urban uses. It is often difficult to establish vegetation on steep channel side slopes and infertile spoil. Special techniques such as mulching, special plants, and unusual maintenance techniques may be required. Without vegetation, erosion and sedimentation are a problem. Intensive management measures may also be necessary to maintain design capacity. Native plants can be used for beautification and require minimum establishment and maintenance. Some trees that can be used for this purpose are: bald cypress, button mangrove (buttonwood) (*Conocarpus erectus*), loblolly bay (*Gordonia lasiathus*), pond cypress, red maple, South Florida slash pine (*Pinus elliottii* var. *densa*), and sweet gum (*Liquidambar styraciflua*). Some of the shrubs are: buttonbush, coco plum (*Chrysobalanus icaco*), dahoon holly (*Ilex cassine*), and wax myrtle. Some herbs include asters, golden canna (*Canna flaccida*), cardinal flower (*Lobelia cardinalis*), pineland lily (*Lilium catesbaei*), ferns, coneflowers (*Rudbeckia* spp.), cattails (*Typha* spp.), rose mallow (*Hibiscus* spp.), and meadow beauty (*Rhexia* spp.).

SALT MARSH (ECOLOGICAL COMMUNITY NO. 18)

Range: The Salt Marsh community occurs along the Atlantic and Gulf Coasts, and inland along tidal rivers. An extensive area occurs along the Gulf of Mexico north of Tarpon Springs to St. Marks. Smaller isolated areas occur inland where salt springs rise near rivers. This community appears as an open expanse of grasses, sedges, and rushes. Usually there is a matrix of interconnected shallow natural channels that aid tidal influx.

Soils: Soils commonly associated with this community are nearly level and very poorly drained. They can be muck or sandy clay loams underlain by loamy sand, or organic soils underlain by clay or sand, or clayey throughout. Many of the soils have a high sulfur content. Some of the soils are soft and will not support the weight of a man or large animal. Tidal action causes saturation of the soil with salt water and inundation to a depth of a few inches. Representative soils include Estero and Wulfert.

Vegetation: Plant species often occur in distinct zones as a result of differing mean water levels and salinity concentrations. Some species, such as black needlerush (*Juncus roemeiranus*) and seashore saltgrass (*Distichlis spicata*), have a wide tolerance range and may be found throughout the grass marsh. Smooth cordgrass (*Spartina alterniflora*) is more indicative of low, regularly flooded marsh, while the high marsh supports: sea myrtle (*Baccharis halimifolia*), marsh hay cordgrass (*Spartina patens*), marsh elder (*Iva* spp.), saltwort (*Batis maritima*), and sea oxeye (*Borrichia spp.*). Along

the Gulf Coast most marshes are dominated by black needlerush. Other plants that characterize the salt marsh community are: sea blite (*Suaeda linearis*), sea purslane (*Sesuvium portulacastrum*), and cordgrasses (*Spartina* spp.).

Wildlife: Salt marshes are good habitat for a variety of wildlife. The habitat type is usually maintained by natural forces such as tidal action and periodic hurricanes. Storms usually cause the creation of "open" water in salt and brackish marshes and also may change salinities. The resulting effect is that plant succession is set back and more favorable habitat may be created for waterfowl, furbearers, and some other forms of wildlife such as wading birds. Artificially created dikes to control salinity are used in managing marsh plants for wildlife. Prescribed burning is also a technique used in marsh management.

The salt marshes support a variety of wildlife. Some common species that occur are: white tail Deer (*Odocoileus virginianus*), raccoons (*Procyon lotor*), river otters (*Lutra canadensis*), pelicans, coots, egrets, gulls, terns, many forms of waterfowl. Protected species include: the West Indian manatee (*Trichechus manatus latirostris*), Cape Sable seaside sparrow (*Ammodramus maritimus mirabilis*, Collier, Monroe, and Miami-Dade Counties only), least tern (*Sterna antillarum*); peregrine falcon (*Falco peregrinus tundrius*), roseate tern (*Sterna dougallii*), bald eagle (*Haliaeetus leucocephalus*), wood stork (*Mycteria americana*), Atlantic green turtle (*Chelonia mydas mydas*), Atlantic hawksbill turtle (*Eretmochelys imbricata imbricata*), American alligator (*Alligator mississippiensis*), Florida ribbon snake (*Thamnophis sauritus sackeni*, Lower Keys population), and the Atlantic saltmarsh water snake (*Nerodia fasciata taeniata*).

Environmental Value as a Natural System: The functions of salt marshes are probably the most important and least understood of all ecological communities. On low energy coastlines and estuaries, the marsh functions as a transition zone from terrestrial to oceanic life. Salt marshes also perform an important function in the stabilization and protection of shorelines, especially during storm tides.

Nutrients, sediments and detritus from upland systems are redistributed by tidal action, making the marsh one of the most productive natural ecological systems. The area serves as a habitat for the early life stages of numerous ocean species as they feed on countless invertebrate organisms. Many wildlife forms overlap normal ranges at least seasonally to become harvesters and, in many cases, part of the natural food chain.

Rangeland: Salt marshes have a potential for producing significant amounts of cordgrass, saltgrass, and other grasses and forbs. For sites in excellent condition, the average annual production of air-dried plant materials varies from 4,000 to 8,000 pounds per acre, depending on plant growth conditions. From three to more than fifteen acres are usually needed per animal unit depending upon amount and type of forage available. The relative percentage of annual vegetative production by weight is 90 percent grasses, 5 percent shrubs and trees, and 5 percent herbaceous plants and vines.

Woodland: These soils are unsuitable for commercial wood production.

Urbanland: This community is subject to a high water table and periodic flooding. Therefore, it has very severe limitations for urban development. Very elaborate water management systems are required for urban uses. It is difficult to establish salt tolerant vegetation on steep channel side slopes and infertile spoil. Special techniques such as mulching, and unusual seeding and management techniques, will be required. Without vegetation, erosion and sedimentation become a problem. Intensive measures may also be required to maintain design capacity. Native plants can be used for beautification and require minimum establishment and maintenance. Some of the trees and shrubs are: black mangrove (*Avicennia germinans*), button mangrove (buttonwood) (*Conocarpus erectus*), necklace pod (*Sophora tomentosa*), sea oxeye, southern red cedar (*Juniperus silicicola*), and white mangrove (*Laguncularia racemosa*). Some of the herbaceous plants are: asters and goldenrod (*Solidago spp.*). Some of the grasses are: cordgrasses, seashore dropseed (*Sporobolus virginicus*), and seashore saltgrass.

SAWGRASS MARSH (ECOLOGICAL COMMUNITY NO. 24)

Range: The Sawgrass Marsh ecological community occurs south of Lake Okeechobee in the historic Everglades Basin. This community covers many thousands of acres. Smaller sawgrass marshes are found outside of this area, but they are included in the Freshwater Marsh and Ponds ecological community (#25).

Soils: Soils commonly associated with this community are nearly level and very poorly drained organic surfaces underlain by limestone. Representative soils are Torry and Terra Ceia.

Vegetation: The natural vegetation of this community is dominated by sawgrass. Muhly grass (*Muhlenbergia capillaris*) increases and becomes obvious when the sawgrass is repeatedly exposed to fire and the hydroperiod is shortened. With natural conditions, the vigorous sawgrass is 6 to 10 feet tall and of such density that few other plants can survive. Other marsh plants invade where marginal conditions occur for sawgrass growth, such as shallow organic soils and areas where the period of water submergence is short. Trees are not characteristic of this community, but a few may occur on the banks of gator holes. Plants that characterize this community are: sawgrass, gulf muhley (*Muhlenbergia capillaris* var. *filipes*), plume grass (*Erianthus spp.*), and pickerelweed (*Pontederia cordata*).

Wildlife: Numerous birds use this community year-round or for over-wintering. Frogs, snails, and crayfish are common and serve as food for larger animals. Animals that commonly occur in this community include: white tail (*Odocoileus virginianus*), red-winged blackbirds (*Agelaius phoeniceus*), egrets, herons, ibis, bitterns, and water snakes. Protected species that may be found in or around the sawgrass community include: Everglades mink (*Mustela vison evergladensis*), Florida panther (*Felis concolor coryi*), snail kite (*Rostrhamus sociabilis*), wood stork (*Mycteria americana*), and American alligator (*Alligator mississippiensis*).

Environmental Value as a Natural System: The sawgrass marshes serve as filter systems for water. They protect natural bodies of water from eutrophication. Marshes can help moderate drought and flood events. Their principal environmental values are related to water quality and quantity. Tall, dense sawgrass occurs in deep organic soils and requires water coverage of the rhizomes for most of the year. It also forms extensive, but shorter and less dense stands on marl soils in South Florida. Drainage, organic soil subsidence, and fires have reduced the amount of sawgrass and promoted the growth of other plants in many areas. Although the sawgrass community is one of the most resistant communities to change under natural conditions, severe fires and water quality reduction can completely alter the community's characteristics within 10 to 20 years.

Rangeland: This site provides little to no native forage values.

Woodland: This community is not generally recommended for woodland.

Urbanland: This community is subject to very high water tables and has severe limitations for urban development. Intensive and complex water management systems are required for urban uses. It is often difficult to establish vegetation on steep channel side slopes and infertile spoil. Special techniques are usually required in these situations. Without vegetation, erosion and sedimentation can become a problem. Much of the sawgrass marsh is now included in public lands and is not available for urban uses.

FRESHWATER MARSH AND PONDS (ECOLOGICAL COMMUNITY NO. 25)

Range: The Freshwater Marsh and Ponds ecological community occurs throughout Florida. Individual communities vary widely in size. The largest communities, several thousand acres in size, generally occur in southeast Florida.

Soils: Soils commonly associated with this community are nearly level and very poorly drained with organic surfaces underlain by sand. Representative soils include Hontoon, Sanibel, and Okeelanta.

Vegetation: Within Florida, eight major different types of freshwater marshes have been described. Any one marsh may be composed of combinations of different major types. The types are: flag marshes, sawgrass marshes, arrowhead marshes, fire flag and other nongrass herbs marshes, cattail marsh, spike-rush marsh, bulrush marsh, and maidencane marsh. Plants that characterize this community may include: Beak rushes (*Rhynchospora spp.*), bulrushes (*Scirpus spp.*), maidencane (*Panicum hemitomon*), sawgrass (*Cladium jamaicense*), spike rushes (*Eleocharis spp.*), arrowhead (*Sagittaria spp.*), cattail (*Typha spp.*), pickerelweed (*Pontederia cordata*), and primrose willow (*Ludwigia spp.*).

Wildlife: Freshwater marshes and ponds provide excellent habitat for many wildlife species. Numerous birds and waterfowl use this community for over-wintering or year-round. Animals that commonly occur in this community are: river otters (*Lutra*

canadensis), raccoon (*Procyon lotor*), marsh rabbits (*Sylvilagus palustris*), deer (*Odocoileus virginianus*), Florida water rat (*Neofiber alleni*), herons, egrets, bitterns, ibis, rails, limpkins (*Aramus guarauna*), snipes (*Gallinago* spp.), killdeer (*Charadrius vociferus*), ducks, hawks, frogs, turtles, and snakes. Some protected animal species that may be found in this ecological community include: Everglades mink (*Mustela vison evergladensis*), Key Vaca raccoon (*Procyon lotor auspicatus,* middle Florida Keys only), silver rice rat (*Oryzomys agentatus*), Cape Sable seaside sparrow (*Ammodramus maritimus mirabilis*), crested caracara (*Polyborus plancus audubonii*), Florida sandhill crane (*Grus canadensis pratensis*), snail kite (*Rostrhamus sociabilis*), wood stork (*Mycteria americana*), American alligator (*Alligator mississippiensis*), Florida ribbon snake (*Thamnophis sauritis sackeni,* Keys population only), and Keys mud turtle (*Kinosternon bauri bauri,* Keys population only).

Environmental Value as a Natural System: Freshwater marshes and ponds serve as filter systems for rivers and lakes. This protects these waterbodies from eutrophication and provides the marsh with nutrients that are used in vegetative growth. Marshes can reduce the impacts of drought and flooding. Fire and water level fluctuations are the major factors affecting these wetland areas. Variations in the water patterns on the marsh will change the plant diversity and productivity. Marsh-prairie systems will eventually move to a woody community with exclusion of fire or with permanent and lower water level changes. The freshwater marsh community is highly endangered. Many have been destroyed or at least degraded. Some examples of areas where drainage has occurred for reclamation of land and for agricultural interests are: The Everglades, Kissimmee River marshes, Lake Isotokpoga marsh, and the Upper St. Johns River marsh. Recreational uses of this community can cause much disturbance and may alter the plant community.

Rangeland: This ecological community has the potential for producing significant amounts of high-quality forage. For sites in excellent condition, the average annual production of air-dried plant materialvaries from 5,000 to 10,000 pounds per acre, depending on plant growth conditions. From three to more than thirteen acres are usually needed per animal unit depending upon amount and type of forages available. The relative percentage of annual vegetative production by weight is 80 percent grasses and grass-like plants, 5 percent trees and shrubs, and 15 percent herbs.

Woodland: This community is not generally recommended for woodland, unless drainage has been provided.

Urbanland: This community is subject to periodic flooding and has severe limitations for urban development. Intensive and complex water management systems are required for urban uses. It is often difficult to establish vegetation on steep channel side slopes and infertile spoil. Special techniques are usually required in these situations, such as mulching, special plants, and unusual management. Without vegetation, erosion and sedimentation can become a problem. Native plants can be used for beautification and require minimum establishment and maintenance. Some of the trees are: buttonbush (*Cephalanthus occidentalis*), coastal plain willow (*Salix caroliniana*), and persimmon (*Diospiros virginiana*). Some of the shrubs are elderberry (*Sambucus canadense*) and wax

myrtle (*Myrica cerifera*). Some of the herbs are: golden canna (*Canna flaccida*), cardinal flower (*Lobelia cardinalis*), coneflowers (*Rudbeckia* spp.), marsh pink (*Sabatia* spp.), and meadow beauty (*Rhexia* spp.).

SLOUGH (ECOLOGICAL COMMUNITY NO. 26)

Range: The Slough ecological community occurs throughout central and southern Florida, but mostly in the latter. Individual communities vary widely in size. Most serve as drainage-ways between depressionsl soilsfor water during periods of heavy and prolonged rainfall. This slough community occurs in a slightly lower position adjacent to the South Florida Flatwoods ecological community (#6) and slightly higher positions adjacent to depressional communities.

Soils: Soils commonly associated with this community are nearly level and poorly drained with sandy marine sediments throughout the profile. Representative soils include Basinger, Malabar, and Riviera.

Vegetation: This community appears as an open expanse of grasses, sedges, and rushes with scattered pines and cypress in an area where the surface soil is saturated during the wet season. Surface water may move over this area for up to a few weeks during the rainy season. Most sloughs are relatively long and narrow and slightly lower in elevation than the surrounding flatwoods or hammocks. Grasses are the most common plants found in sloughs. Plants that characterize this community are: St. Peters wort (*Ascyrum stans*), pickerelweed (*Pontederia cordata*), sundew (*Drosera spp.*), marsh pink (*Sabatia spp.*), meadow beauty (*Rhexia spp.*), milkwort (*Polygala spp.*), beak rushes (*Rhynchospora spp.*), blue maidencane (*Amphicarpum muhlenbergianum*), and sloughgrass (*Scleria spp.*).

Wildlife: This community is productive in regards to food for bobwhite quail (*Colinus virginianus*), deer (*Odocoileus virginianus*), and wading birds. Its low-growing vegetative growth provides poor cover for most wildlife species, but this is often offset by the "edge effect" of this community when it is located with flatwoods. Sloughs are host to a diverse wildlife population. Many larger animals occur where sloughs join flatwoods and hammocks. Typical animals of the sloughs are: Bobcat (*Lynx rufus*), gray fox (*Urocyon cinereoargenteus*), marsh rabbit (*Sylvilagus palustris*), opossum (*Didelphis virginiana*), cotton rat (*Sigmodon hispidus*), raccoon (*Procyon lotor*), egrets, herons, ibis, meadowlark (*Sturnella* spp.), hawks, snipes (*Gallinago* spp.), snakes, and frogs. Some of the threatened or endangered animals include the Florida panther (*Felis concolor coryi*) and the Florida sandhill crane (*Grus canadensis pratensis*).

Environmental Value as a Natural System: Sloughs serve as natural drainageways during high water periods. They also retain water, help slow down water flows, and thereby increase water quantity and improve water quality. Fire and artificial water level fluctuations are the major factors affecting these areas. Variations in the natural sequences of either event will change the slough's diversity and productivity. With

the exclusion of fire or permanent water level reduction, the plant succession will be to a wooded community.

Rangeland: Native forage production is good with proper management. Use for rangeland has only a slight effect on the community if properly managed. The community has good wildlife values, especially with proper management. The installation of water control practices have facilitated the use of some sloughs for improved pasture, vegetables, and citrus. This ecological community has the potential for producing significant amounts of high quality forage such as: blue maidencane (*Amphicarpum muhlenbergianum*), chalky bluestem (*Andropogon capillipes*), and bluejoint panicum (*Panicum tenerum*). For sites in excellent condition, the average annual production of air-dried plant material varies from 4,000 to 8,000 pounds per acre. This variation depends on plant growth conditions. From three to more than 16 acres are usually needed per animal unit depending upon amount and type of forage available. The relative percentages of annual vegetative production by weight is 90 percent grasses and grass-like plants, 10 percent herbaceous plants.

Woodland: This community is not generally recommended for commercial woodland, unless drainage has been provided.

Urbanland: This community is subject to high water tables, especially during the rainy season. This causes limitations for urban development and water management systems are required. It is often difficult to establish vegetation on steep channel side slopes and infertile spoil. Special planting techniques are usually required. Without adequate vegetation, erosion and sedimentation is usually a problem. Severe wind erosion can also occur, especially in the spring. Native plants can be used for beautification and require minimum establishment and maintenance. Some of the shrubs are: saw palmetto (*Serenoa repens*) and wax myrtle (*Myrica cerifera*). Some of the herbs are: asters, coneflowers (*Rudbeckia* spp.), marsh pink (*Sabatia* spp.), and meadow beauty (*Rhexia* spp.).

Appendix E
NATURAL SOIL LANDSCAPE POSITIONS CLASSIFICATION DATABASE

This database contains 35 soil data fields (1999 update). The data table contains fields from the SSURGO COMP table and the FOTG table, with one field added for the Natural Soil Landscape Position code. One notable change from the SSURGO COMP table is that only the Sequence Number 1 soils have been included in this table, since that component is most extensive and multiple per map unit are not user friendly. Within the table, an entry of "NA" (in text fields) or "-8" (in numeric fields) indicates that there is no data associated with this field for that entry ("not applicable"). An entry of "ND" (in text fields) or "-9" (in numeric fields) indicates that there is no data available for that entry, although there could be some available at a later update. The Soil Data Table elements are defined as follows.

MUID

This is the Map Unit Identification symbol, which uniquely identifies a map unit within a state. It is a six digit symbol derived from a concatenation of the three digit soil survey area symbol (SSAID) and the three digit map unit symbol (MUSYM). Thus the six digit code for Oldsmar sand (025 = soil survey code suffix for Oldsmar Sand) in Palm Beach County (611 = SSAID prefix code for Palm Beach County) is 611025. Note that some units may only have five digits. This occurs when a six-digit MUID, such as 061025, is truncated to 61025 when the first number is zero. A listing of three digit county codes used in SSURGO and in our Soil Classification Database is found in at the end of this section.

STSSAID

A concatenation of the alpha code for a state (FIPS) and the soil survey area symbol (SSAID).

MUSYM

This is the soil survey Map Unit Symbol. It is a three digit map unit code designated for each map unit name within a county.

CNTYABBR

This field contains a two-letter abbreviation for the county.

Table E-1. Three Digit Map Unit Symbols Used in the MUID.

Florida County	Three Digit SSAID Symbol
Broward	716
Charlotte	015
Collier	021
Dade	025
De Soto	027
Glades	043
Hardee	049
Hendry	051
Highlands	055
Indian River	061
Lee	071
Martin	753
Monroe	087
Okeechobee	757
Orange	095
Osceola	610
Palm Beach	760
Polk	105
St. Lucie	766

LSPOS CODE

This is the NSLP position in which the MUID is found in **Table E-2**. Detailed descriptions of these categories can be found in the "Classification by NSLP Type" section of this document.

MAP UNIT NAME

This is the full name for the soil series which includes the soil series name(s), texture, percent slope, and phase (if noted).

S5ID 1

This is the Soil Interpretation Record Number for the Sequence Number 1 soil series found within the MUID. It is a six digit code and contains the two letter state code for the state responsible for the soil series phase (FL = Florida, GA = Georgia, etc) plus the four digit code for a particular soil (0059 = Myakka, flatwood). Thus the six digit code for Myakka is FL0059. The two letter state code is the same as used by the U.S. Postal Service for postal delivery.

Table E-2. LSPOS Codes.

LSPOS Code	Description
1	Water
2	Tidal Soils
3	Marl & Rocky Soils
4	Everglades Peat
5	Muck Depressions
6	Sand Depressions
7	Flats Soils
8	Flatwood Soils
9	Knolls
10	Central Ridge & Dunes
11	Urban or Made Lands
12	No Data

COMPPCT 1

This field contains the percent of area of the Sequence Number 1 (first) soil series within the MUID.

SURFTEXT 1

This field contains the surface soil texture code for the Sequence Number 1 (first) soil series found within the map unit (**Table E-3**).

SHWT-HIGH

This is the high value for the average range of the depth to the seasonal high water table. Units are in feet. Negative values indicate a water table above the soil surface.

SHWT-LOW

This is the low value for the average range of the depth to the seasonal high water table. Units are in feet. Negative values indicate a water table above the soil surface.

SHWT-BEG

This is the average month in which the seasonal high water table begins.

SHWT-END

This is the average month in which the seasonal high water table ends.

Table E-3. Surface Soil Texture Codes.

Surface Soil Texture Code	Description
C	clay
FS	fine sand
FSL	fine sany loam
GR-MUCK	gravelly muck
GRV-L	very gravelly loam
LFS	loamy fine sand
LS	loamy sand
MARL	marl
MUCK	muck
MK-FS	mucky fine sand
MK-LFS	mucky loamy fine sand
MK-S	mucky sand
ROCK	rock
S	sand
SCL	sandy clay loam
SICL	silty clay loam
SIL	silt loam

SHWT-DUR

This is the duration of the SHWT in months.

HYDRIC

This indicates if a MAP UNIT NAME is defined as a Hydric soil. If the MAP UNIT NAME is hydric the entry is "Y". If the MAP UNIT NAME is not hydric the entry is "N".

HYDROGRP

This is the Hydrologic Group for a particular MAP UNIT NAME. **Table E-4** contains the codes used with a general description of the soil conditions associated with them.

DRAINAGE

This is the soil drainage class code, which identifies natural drainage condition of the soil. The code refers to the frequency and duration of periods when the soil is free of saturation (**Table E-5**).

Table E-4. Hydrological Group Codes.

Hydrological Group Code	Description
A	High infiltration rates. Soils are deep, well drained to excessively drained sands and gravels
B	Moderate infiltration rates. Deep and moderately deep, moderately well and well drained soils that have moderatly coarse textures
C	Slow infiltration rates. Soils with layers impeding downward movement of water, or soils that have moderately fine or fine textures
D	Very slow infiltration rates. Soils are clayey, have a high water table, or are shallow to an impervious layer

Table E-5. Soil Drainage Class Codes.

Soil Drainage Class Code	Description
E	excessively
SE	somewhat excessively
W	well
MW	moderately well
SP	somewhat poorly
P	poorly
VP	very poorly

ECOLCOMM

This indicates the Ecological Community code of a MAP UNIT NAME. These codes correspond to the ecological communities as defined by the Soil Conservation Society's document "The 26 Ecological Communities of Florida".

MLRA

This is the Major Land Resource Area. It is a three digit numeric code or four digit numeric and alpha code that indicates the Major Land Resource Area code of a MAP UNIT NAME. MLRAs are areas that have similar land use, topography, climate, precipitation, and soils.

MUKIND

This is the code identifying the kind of map unit, for example: Consociation (C); Association (A); Undifferentiated Group (U); Complex (X).

ANFLOOD FREQ

Descriptive term used to describe the frequency of annual flooding (flooding likely to occur during the year) that is likely to occur. Frequent (FREQ) ->50% chance of flooding; Occasional (OCCAS) - 5 to 50% chance of flooding; Rare (RARE) - 0 to 5% chance of flooding.

ANFLOOD BEG

Month in which the annual flooding (flooding likely to occur during the year) begins in a normal year.

ANFLOOD END

Month in which the annual flooding (flooding likely to occur during the year) ends in a normal year.

ROCKDEPTH HIGH

The maximum value for the range in depth to the bedrock, expressed in inches.

ROCKDEPTH LOW

The maximum value for the range in depth to the bedrock, expressed in inches.

SLOPE LOW

This is the lower end of the slope range for a MAP UNIT NAME. It is a one or two digit numeric value expressed in percent. A difference in elevation of one foot over a horizontal distance of one hundred feet is one percent. Additional Information can be found in the National Soils Handbook.

SLOPE HIGH

This is the upper end of the slope range for a MAP UNIT NAME. It is a one or two digit numeric value expressed in percent. A difference in elevation of five feet over a horizontal distance of one hundred feet is five percent.

PANDEPTHHIGH

Maximum value for the range in depth to the upper boundary of a cemented pan, expressed in inches.

PANDEPTHLOW

Minimum value for the range in depth to the upper boundary of a cemented pan, expressed in inches.

PANHARD

The degree of induration and thickness of the cemented pan. A pan is rated as "THICK" if it is more than 3 inches thick and continually indurated or more than 18 inches thick and discontinuous or fractured. Pans not meeting these criteria are rated THIN.

OTHERPH

This is Soil Series Phase Criteria that is used in conjunction with the Soil Interpretation Record (S5ID) to provide the correct interpretations for a particular MAP UNIT NAME. Additional Information concerning OTHERPH is in the National Soils Handbook.

LEACH

This indicates the potential of a MAP UNIT NAME to allow chemicals to leave the application site by leaching through the soil. Possible entries are LOW, MEDIUM, or HIGH. Additional information concerning soileach and other types of Water Quality Interpretations is in Section II-iii-L of the FOTG.

RUNOFF

This indicates the potential of a MAP UNIT NAME to allow chemicals to leave the application site with runoff water and/or detached soil particles. Possible entries are LOW, MEDIUM, or HIGH. Additional information concerning soilrun and other types of Water Quality Interpretations is in Section II-iii-L of the FOTG.

CORCON

An interpretation of the rating of the susceptibility of concrete to corrosion when in contact with the soil.

CORSTEEL

An interpretation of the rating of the susceptibility of uncoated steel to corrosion when in contact with the soil.

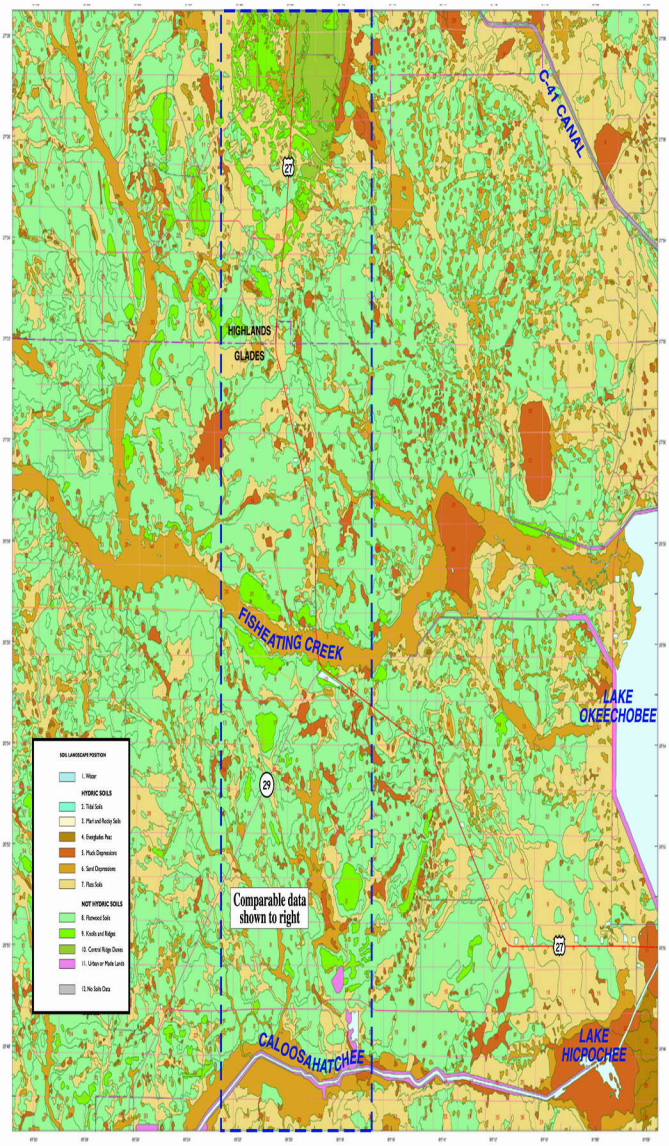
NATURAL SOIL LANDSCAPE POSITIONS

The Natural Soil Landscape Positions (NSLP) are a reclassification of 19 county soil surveys published by the Natural Resource Conservation Service (NRCS), formerly the Soil Conservation Service. A total of 909 soil map units were reclassed into 12 categories based on the depth of the seasonal high-water table, soil morphological characteristics, and geographical location. This reclassification was undertaken to simplify the complex, multi-county soil survey data and to promote a clearer understanding of the relationships that exist between soil, hydrology, and vegetation community. The resulting data offers the benefit of a seamless spatial soil landscape layer within the South Florida Water Management District's (SFWMD) Geographical Information System (GIS).

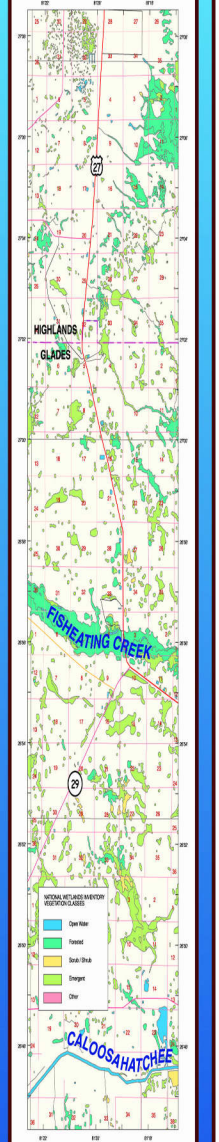
One product of this soil reclassification is a map layer, a section of which is presented here with corresponding maps for comparison from the National Wetlands Inventory and United States Geological Survey, as well as a LANDSAT image. The NSLP map interprets the landscape through soil morphology and corresponding hydrological conditions under which it formed. This is valuable in understanding natural relationships between adjacent landscapes, regional patterns of hydrology, historic conditions, and relative topographical gradients. Below, each of the landscape positions are explained in detail. Within each box, there is text describing the landscape position, a photo illustrating a typical vegetation community, and graphics. The graphics display the seasonal high water table ranges for depth in feet and duration in months.

This project was a cooperative effort between the SFWMD and the NRCS. Funding was provided as part of the United States Environmental Protection Agency's grant to the SFWMD for the Comprehensive Conservation Permitting and Mitigation Strategy Wetland Strategies. The SFWMD provided GIS, graphical, and planning support. Ken Liudahl, NRCS soil scientist, developed the concept, provided data interpretation, and quality control. A previous cooperative effort between the SFWMD and the NRCS was the creation of a county soil survey digital database (SSURGO) and a seamless GIS soil survey coverage for 19 counties in South Florida. For more information contact project manager Jerry Krenz at the SFWMD, (561) 682-6746 or via e-mail: jkrenz@sfwmd.gov or Soil Scientist Ken Luidahl at the NRCS, (561) 439-1770. More detailed information about this project can be found on our webpage at www.sfwmd.gov/org/pld/proj/wetcons.

County Soil Survey Data Reclassed to Landscape Positions

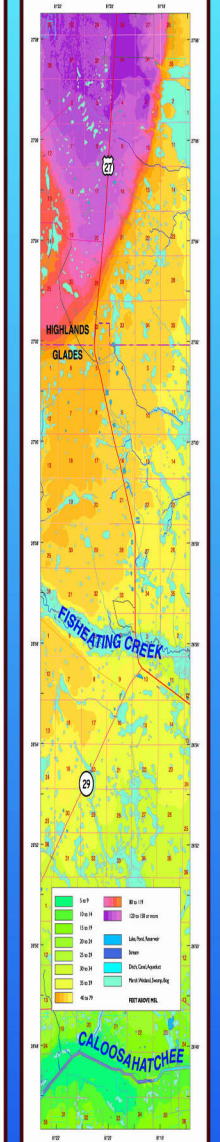


SFWMD National Wetlands Inventory



1994 Thematic Mapper Satellite

USGS Topography & Hydrology



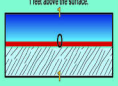
1. WATER

Permanently flooded.
Includes freshwater, saltwater, natural, and excavated sites.

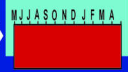
2. TIDAL SOILS

- Very poorly-drained.
- Hydric soils.
- Mineral or organic surfaces.
- Examples of these soils include Wulfert, Durbin, and Pecklish.
- Found along coastal areas in salt marshes, mangrove or tidal swamps, and areas adjacent to the Intracoastal Waterway that have tidal flooding influence.

Includes beaches.
Water-table ranges from 1 foot below to 1 foot above the surface.



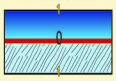
Water-table duration is 12 months.
The water table is subject to tidal influences for the entire year.



3. MARL & ROCKY SOILS

- Poorly to very poorly-drained.
- Hydric soils.
- Calcitic muds or rocky surface.
- Examples of these soils include Biscayne, Perrine, and Rock Outcrop.
- Marl and Rocky soils occur in Miami-Dade, Monroe, and Collier counties along the southern extent of the Everglades.

SHWT ranges from 1 foot below to 1 feet above the soil surface.

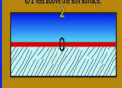


SHWT duration is 4 to 7 months.
The end of the SHWT ranges from September to December and typically ends by November.

4. EVERGLADES PEAT

- Very poorly-drained.
- Hydric soils.
- Organic.
- Examples of these soils include Pahokee, Terra Ceia, and Lauderhill.
- Normally found within the extent of the historic Everglades Basin.

SHWT ranges from the soil surface to 2 feet above the soil surface.



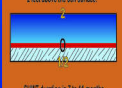
SHWT duration is 8 to 11 months.
The end of the SHWT ranges from February to April and typically ends in April.

5. MUCK DEPRESSION

- Very poorly-drained.
- Hydric soils.
- Organic surface layer underlain by sandy marine sediments.
- Examples of these soils include Sunsuls, Gator, and Hontoon.

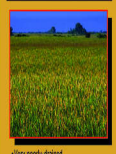
Includes frequently flooded alluvial soils whose SHWT may fall outside the category hydrologically.

SHWT ranges from 1/2 foot below to 2 feet above the soil surface.



SHWT duration is 7 to 11 months.
The end of the SHWT ranges from December to April and typically ends in April.

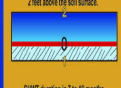
6. SAND DEPRESSION



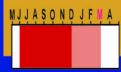
- Very poorly-drained.
- Hydric soils.
- Sandy marine sediments throughout the profile.
- Typical depressional soils are Riviera, Boca, and Basinger.
- Typically these are depressions adjacent to flats and flatwood landscapes.

Includes frequently flooded alluvial soils whose SHWT may fall outside the category hydrologically.

SHWT ranges from 1 foot below to 2 feet above the soil surface.



SHWT duration is 7 to 10 months.
The end of the SHWT ranges from December to March and typically ends in March.



7. FLATS SOILS

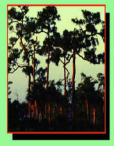
- Poorly-drained.
- Not-hydric.
- Sandy marine sediments throughout the profile.
- Examples of these soils include Basinger, Riviera, Manatee, and Pineda.
- Located between the depressional and flatwood landscapes, and are generally regarded as transitional areas.

Includes occasionally flooded alluvial soils whose SHWT may fall outside the category hydrologically.

SHWT ranges from the soil surface to 1 foot below the surface.

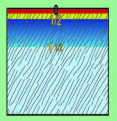
SHWT duration is 4 to 10 months.
The end of the SHWT ranges from September to March and typically ends in February.

8. FLATWOOD SOILS



- Poorly-drained.
- Not-hydric.
- Sandy marine sediments throughout the profile.
- Examples of these soils include Myakka, Immokalee, and Smyrna.
- Most of these soils series have a sub-surface spodic horizon.

SHWT ranges from 1/2 foot below to 1 1/2 feet below the soil surface.

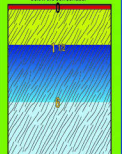


SHWT duration is 4 months.
The SHWT ends in September.

9. KNOLLS

- Somewhat poorly to well-drained.
- Not-hydric.
- Sandy marine sediments throughout the profile.
- Examples of these soils include Tavares, Arome, Zolfo, and Pomello.

SHWT ranges from 1 1/2 to 6 feet below the soil surface.

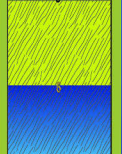


SHWT duration is 4 to 7 months.
The SHWT typically ends in November.

10. CENTRAL RIDGE-DUNES

- Excessively-drained.
- Not-hydric.
- Sandy marine sediments throughout the profile.
- Examples of these soils include Candler, Astatula, and Neilhurst.

The water table is more than 6 feet below the soil surface.



The SHWT is typically more than 6 feet below the surface for the entire year.

11. URBAN OR MADE LANDS

Urban or Made Lands are soils which have been excavated or disturbed and no longer retain their natural morphological features.

SHWT ranges from 6 inches to 6 feet below the soil surface. The SHWT is controlled in urban areas and varies greatly .

Seasonal High Water Table (SHWT) is the shallowest depth to free water that stands in an unlined borehole or where the soil moisture tension is zero for a significant period (more than a few weeks). Depth ranges are displayed to the right.

Duration is defined as the length of time that the SHWT expresses itself. The SHWT begins at the onset of the rainy season, typically in May or June duration of the rainy season and the Natural Landscape Position. Duration calendars are displayed to the right.

This project was a cooperative effort between the SFWMD and NRCS, formerly the Soil Conservation Service. This project has been funded in part by the United States Environmental Protection Agency under Assistance Agreement ID Number X9948984-96-0 to the South Florida Wetlands Conservation Strategy.
